

HOMOTOPY HYPERBOLIC 3-MANIFOLDS ARE HYPERBOLIC

David Gabai, G. Robert Meyerhoff, and Nathaniel Thurston

Section 0: Introduction

This paper introduces a rigorous computer-assisted procedure for analyzing hyperbolic 3-manifolds. This technique is used to complete the proof of several long-standing rigidity conjectures in 3-manifold theory as well as to provide a new lower bound for the volume of a closed orientable hyperbolic 3-manifold.

Theorem 0.1: Let N be a closed hyperbolic 3-manifold. Then

- 1) If $f: M \rightarrow N$ is a homotopy equivalence where M is a closed irreducible 3-manifold, then f is homotopic to a homeomorphism.
- 2) If $f, g: M \rightarrow N$ are homotopic homeomorphisms, then f is isotopic to g .
- 3) The space of hyperbolic metrics on N is path connected.

Remarks: Under the hypothesis that M is hyperbolic, conclusion i) follows from Mostow's rigidity theorem [Mo]. Under the hypothesis that N is Haken, conclusions i)-ii) follow from Waldhausen [W]. If N is both Haken and hyperbolic, then iii) follows by combining [Mo] and [W]. Since non-Haken manifolds are necessarily orientable we will from now on assume that all manifolds under discussion are orientable.

Theorem 0.1 with the added hypothesis that a closed geodesic $\delta \subset N$ has a *non coalescable insulator family* was proven by Gabai (see [G]). Thus Theorem 0.1 follows from [G] and the main technical result of this paper which is,

Theorem 0.2: If δ is a shortest geodesic in a closed orientable hyperbolic 3-manifold, then δ has a non-coalescable insulator family.

Remarks: If δ is the core of an embedded hyperbolic tube of radius $(\ln 3)/2 = 0.549306\dots$ then δ has a non-coalescable insulator family by Lemma 5.9 of [G]. In this paper we establish a second condition, sufficient to guarantee the existence of a non-coalescable insulator family for δ . That is if $\text{Corona}(\delta) < 2\pi/3$. ($\text{Corona}(\delta) < 2\pi/3$ if tube radius(δ) $> (\ln 3)/2$). We use the expression “ N satisfies the *insulator condition*” when there is a geodesic δ which has a non-coalescable insulator family.

We prove Theorem 0.2 by first showing that all closed hyperbolic 3-manifolds, with seven families of exceptional cases, have embedded hyperbolic tubes of radius $(\ln 3)/2$ about their shortest geodesics. Conjecturally, up to isometry, there are exactly six exceptional manifolds (see Conjecture 4.2). Second, we show that any shortest geodesic δ in six of the seven families has $\text{Corona}(\delta) < 2\pi/3$. Finally, we show that the seventh family corresponds to Vol3, the third smallest known hyperbolic 3-manifold, and that the insulator condition holds for Vol3. Each of the three parts of the proof is carried out with the assistance of a rigorous computer program.

Here is a hint why Theorem 0.2 might be amenable to computer proof. If a shortest geodesic δ in a hyperbolic 3-manifold N does not have a $(\ln 3)/2$ tube then there is a 2-generator subgroup G of $\pi_1(N) = \Gamma$ which also does not have that property. That is, after identifying $N = \mathbf{H}^3/\Gamma$ and letting $Z = \mathbf{H}^3/G$, then a shortest geodesic in Z does

not have a $(\ln 3)/2$ tube. G is a group of 2 generators, generated by f and w , where $f \in \Gamma$ is a primitive hyperbolic isometry whose fixed axis $\delta_0 \subset \mathbf{H}^3$ projects to δ , and w is an isometry of $\mathbf{H}^3$ which takes δ_0 to a nearest translate. Here δ_0 is a lift of δ to $\mathbf{H}^3$.

The space of relevant 2-generator groups in $\text{Isom}(\mathbf{H}^3)$ naturally lives in $\mathbf{C}^3$. We show that except for seven small regions in $\mathbf{C}^3$ the shortest geodesic in any discrete, torsion free, parabolic free 2-generator group must have a $(\ln 3)/2$ tube. Further, if $\text{Corona}(\delta) \geq 2\pi/3$, then there is a 2-generator subgroup with that property. That is, there is a 2-generator subgroup G of $\pi_1(N)$ such that if $N_1 = \mathbf{H}^3/G$, then $\text{Corona}(\delta_1) = \text{Corona}(\delta) \geq 2\pi/3$ for some shortest geodesic δ_1 in N_1 . We show that away from a single small open set in $\mathbf{C}^3$, every discrete, torsion free, parabolic free 2-generator group G satisfies $\text{Corona}(\delta) < 2\pi/3$, where δ is a shortest geodesic in $\mathbf{H}^3/G$. We finally show that the exceptional open set contains a unique manifold which is Vol3. In fact we show that if a shortest geodesic δ in N satisfies $\text{Corona}(\delta) > 2\pi/3$, then $N = \text{Vol3}$. A variant of the above arguments shows that Vol3 satisfies the insulator condition.

This paper is organized as follows. In Chapter 1 we describe a space $\mathcal{P}' \subset \mathbf{C}^3$ which naturally parametrizes all relevant 2-generator groups. We explain how a theorem of Meyerhoff as well as elementary hyperbolic geometry considerations imply that we need only consider a compact portion $\mathcal{P}$ of $\mathbf{C}^3$. We explain in detail the plan for proving Theorem 0.2. We will actually be working in the parameter space $\mathcal{W} = \exp(\mathcal{P})$. The technical reasons for working in $\mathcal{W}$ is described at the end of this section. In Chapter 2 we describe and prove the necessary results about the Corona function. In Chapter 3 we prove that the exceptional open set in $\mathbf{C}^3$ contains only Vol3. Also if δ is a shortest geodesic in a closed orientable hyperbolic 3-manifold N and $\text{Corona}(\delta) \geq 2\pi/3$, then $N = \text{Vol3}$. Nonetheless, we are able to show that Vol3 satisfies the insulator condition. In Chapter 4, we prove some applications, one of which is discussed briefly below.

In Chapters 5 through 8 we address the computer-related aspects of the proof. Here, the method for describing the decomposition of the parameter space $\mathcal{W}$ into sub-regions is given, and the conditions used to eliminate all but seven of the sub-regions are discussed. At the end of this chapter, the first part of a detailed example is given. Eliminating a sub-region requires that a certain function is shown to be bounded appropriately over the entire sub-region. This is carried out by using a first-order Taylor series approximation of the function together with a remainder bound. Our computer version of such Taylor series with remainder bounds is called an *AffApprox* and in Chapter 6, the relevant theory is developed. At this point, the detailed example of Chapter 5 can be completed.

Finally, in Chapters 7 and 8, round-off error analysis appropriate to our set-up is introduced. Specifically, in Chapter 8, round-off error is incorporated into the *AffApprox* formulas introduced in Chapter 6. The proofs here require an analysis of round-off error for complex numbers, which is carried out in Chapter 7.

We used two rigorous computer programs in our proofs—*verify* and *fudging*. These programs are provided in Appendices 1 and 2. Actually, *fudging* is a variation of *verify* and as such we only provide the sections of *fudging* that are changed. The proofs amount to having *verify* and *fudging* analyze several computer files. These computer files are available from the Geometry Center. Details about how to get them and the programs can be found at

<http://www.geom.umn.edu:/locate/HomotopyHyperbolic>

A consequence of this work is that either the shortest geodesic in a closed orientable 3-manifold N has a $1.059191579962\dots/2$ tube or $N = \text{Vol3}$. The volume of Vol3 is $1.01\dots$ and by [GM2] if N has a $\log(3)/2 = 0.549306\dots$ tube about a geodesic, then the volume of N is greater than $0.16668\dots$. This leaves some exceptional cases that can be analyzed using data provided by *verify*. In any case, we obtain

Theorem 4.5: If N is a closed hyperbolic 3-manifold, then $\text{vol}(N) > 0.16668\dots$

Remark: The best published lower bound for volume is 0.001 by [GM1], which improved the lower bound of 0.0008 of [M2].

Acknowledgements: We thank The Geometry Center and especially Al Marden and David Epstein for the vital and multifaceted roles they played in this work. Jeff Weeks and SNAPPEA provided valuable data and ideas. In fact it was the data from an undistributed version of SNAPPEA that encouraged us to pursue a computer-assisted proof of Theorem 0.2.

Bob Riley specially tailored his program POINCARÉ to directly address the needs of our project. His work provided many leads in our search for killerwords. Further, he provided the first proofs that the six exceptional regions (other than the Vol3 region) correspond to closed orientable 3-manifolds. The authors are deeply grateful for his help.

The first-named author thanks the NSF for partial support. Some of the first author's preliminary ideas were formulated while visiting David Epstein at the University of Warwick Mathematics Institute. The second-named author thanks the NSF for partial support; the USC and Caltech Mathematics Departments for supporting him as a visitor while much of this work was done; and Jeff Weeks, Alan Meyerhoff, and especially Rob Gross for computer assistance. The third-named author thanks the NSF for partial support; and the Geometry Center and the Berkeley Mathematics Department for their support.

Chapter 1: Killer Words and the Parameter Space

Definition 1.1: We will work in the upper-half-space model for hyperbolic 3-space. All isometries will be orientation preserving. If f is an isometry, then we define $\text{Relength}(f) = \inf\{\rho(x, f(x)) \mid x \in \mathbf{H}^3\}$. Thus $\text{Relength}(f) = 0$ if and only if f is either a parabolic or elliptic isometry. If $\text{Relength}(f) \neq 0$, then f is hyperbolic and fixes a unique geodesic σ in $\mathbf{H}^3$. In that case σ is oriented (the negative end being the repelling fixed point on S_∞^2) and the isometry f is the composition of a rotation of $t \pmod{2\pi}$ radians along σ (the sign of the angle of rotation is determined by the right-hand rule) followed by a pure translation of $\mathbf{H}^3$ along σ of $l = \text{Relength}(f)$. We define $\text{length}(f) = l + it$. If σ is an oriented geodesic in $\mathbf{H}^3$, then it makes sense to talk about an $l + it$ translation of $\mathbf{H}^3$ along σ , even when $l \leq 0$.

If f is elliptic, then f is a rotation of t radians about some oriented geodesic. If f is elliptic, we define $\text{length}(f) = |t|i$, the absolute value accounting for the arbitrariness of

the orientation of the fixed geodesic. If f is parabolic or the identity, we define $\text{length}(f) = 0 + i0$. So, for all isometries we have that $\text{Relength} = \text{Re}(\text{length})$.

Definition 1.2: If G is a subgroup of $\text{Isom}(\mathbf{H}^3)$, then we say that f is an element of *smallest length* in G if $\text{Relength}(f) \leq \text{Relength}(g)$ for all $g \in G$, $g \neq \text{id}$.

Convention 1.3: Let B denote the oriented geodesic $t(0, 0, 1)$, with negative end $(0, 0, 0)$. Let C denote the oriented geodesic with negative endpoint $(-1, 0, 0)$ and positive endpoint $(1, 0, 0)$.

Lemma 1.4: If the isometry f is represented by the matrix $A \in \text{PSL}(2, \mathbf{C})$, then

$$\text{length}(f) = 2\text{Arccosh}(\text{trace}(A)/2),$$

where the branch of Arccosh with positive real values is taken, unless the real part is zero in which case the non-negative imaginary part is taken.

Proof: Because trace is a conjugacy invariant, we can normalize our set-up via conjugation and assume that the axis of f is B . As such, A is a diagonal matrix, with diagonal entries p and p^{-1} .

The action of A on the bounding complex plane is simply multiplication by p^2 . Extending this action to upper-half-space in the natural way rotates the z -axis by angle $\arg(p^2)$ and sends $(0, 0, 1)$ to $(0, 0, |p|^2)$. Thus, $\text{Im}(\text{length}(f)) = \arg(p^2) = \text{Im}(\ln(p^2))$ and, using the hyperbolic metric, $\text{Re}(\text{length}(f)) = \ln(|p|^2) = \text{Re}(\ln(p^2))$. That is, $\text{length}(f) = \ln(p^2)$. Thus, we need only show that $2\ln(p) = 2\text{Arccosh}(\text{trace}(A)/2)$. But this follows because $\cosh(\ln(p)) = (p + p^{-1})/2 = \text{trace}(A)/2$. ■

Definition 1.5: If σ, τ are disjoint oriented geodesics in $\mathbf{H}^3$ which do not meet at infinity, then define $\text{distance}(\sigma, \tau) = \text{length}(w)$ where $w \in \text{Isom}(\mathbf{H}^3)$ is the hyperbolic element which translates $\mathbf{H}^3$ along the unique common perpendicular between σ and τ and which takes the oriented geodesic σ to the oriented geodesic τ . The oriented common perpendicular from σ to τ is called the *orthocurve* between σ and τ . The *ortholine* between σ and τ is the complete oriented geodesic in $\mathbf{H}^3$ which contains the orthocurve between σ and τ .

If σ, τ intersect at one point in $\mathbf{H}^3$ then slight changes must be made in the above definition. The ortholine has no natural orientation, the orthocurve is a point, and w is an elliptic isometry.

If σ, τ intersect at infinity, then there is no unique common perpendicular, hence no ortholine, and $\text{distance}(\sigma, \tau) = 0 + i0$, or $0 + i\pi$ depending on whether or not σ and τ point in the same direction at their intersection point(s) at infinity.

Lemma 1.6: $\text{distance}(\sigma, \tau) = \text{distance}(\tau, \sigma)$ ■

Lemma 1.7: If the isometry f is represented by the matrix

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{PSL}(2, \mathbf{C}),$$

then $2\text{distance}(f(B), B) = 2\text{Arccosh}(ad + bc)$. Again, the branch of Arccosh with positive real values is taken, unless the real part is zero in which case the non-negative imaginary part is taken.

Proof: In the case where B and $f(B)$ do not intersect at infinity, we will compute the length of h , the square of the transformation taking B to $f(B)$ along their ortholine. $h = (f \circ \rho \circ f^{-1}) \circ \rho$ where ρ is 180-degree rotation about B and hence $(f \circ \rho \circ f^{-1})$ is 180-degree rotation about $f(B)$. ρ and f are represented by the matrices

$$\pm \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{PSL}(2, \mathbf{C}).$$

Hence, $h = (f \circ \rho \circ f^{-1}) \circ \rho$ can be computed to have representation

$$\begin{pmatrix} ad + bc & 2ab \\ 2cd & ad + bc \end{pmatrix}.$$

Using Lemma 1.3, we have that

$$2\text{distance}(f(B), B) = \text{length}(h) = 2\text{Arccosh}(\text{trace}(h)/2) = 2\text{Arccosh}(ad + bc).$$

If f fixes the point $(0,0,0)$ at infinity, then $c = 0$, $ad = 1$ and the formula holds. Similarly for the other cases in which B and $f(B)$ intersect at infinity. Note that this formula only defines $\text{distance}(f(B), B)$ modulo $i\pi$, but this is sufficient for our purposes. ■

Definition 1.8: Let δ be a geodesic in the hyperbolic 3-manifold N . Then $\text{tuberadius}(\delta) = \sup\{r \mid \text{there exists in } N \text{ an embedded } D^2 \times S^1 \text{ of radius } r \text{ centered about the geodesic } \delta\}$.

Lemma 1.9: Let δ be a geodesic in the hyperbolic 3-manifold N and $\{\delta_i\}_{i \geq 0}$ be the set of its distinct lifts to $\mathbf{H}^3$, then $\text{tuberadius}(\delta) = \min\{\text{Redistance}(\delta_0, \delta_i) \mid i \neq 0\}$. ■

Definition 1.10: We define an open subset $\mathcal{P}'$ of $\mathbf{C}^3$ which naturally parametrizes the collection of conjugacy classes of 2-generator subgroups $G \subset \text{Isom}(\mathbf{H}^3)$ with specified generators f, w where f is hyperbolic and w is not parabolic. By conjugating G we can assume that f is a positive translation of $\mathbf{H}^3$ along the geodesic B , and that the orthocurve from $w^{-1}(B)$ to B lies on C on the negative side of $C \cap B$. Associated to $\{G, f, w\}$, the group G with specified generators f, w , is the parameter $(L, D, R) = (l + it, d + ib, r + ia)$ where $l + it = \text{length}(f)$ and $d + ib = \text{distance}(w(B), B)$. The complex number $r + ia$ is defined as follows. The isometry w is the composition of two isometries, first a $d + ib$ translation of $\mathbf{H}^3$ along C , which takes $w^{-1}(B)$ to B , as oriented geodesics, followed by an $r + ia$ translation along B .

We are primarily interested in the set $\mathcal{T}' \subset \mathbf{C}^3$ which parametrizes all conjugacy classes of triples $\{G, f, w\}$ where G is a group generated by a *shortest* element f which (positively) translates B and $w \in G$ takes B to a *nearest* translate $w(B)$ such that $-\text{Relength}(f)/2 < \text{Redistance}(\text{ortholine from } w^{-1}(B) \text{ to } B, \text{ortholine from } B \text{ to } w(B)) \leq \text{Relength}(f)/2$. By conjugating G we can assume both that f is a positive

Figure 1.1

translation along the geodesic B and that the orthocurve from $w^{-1}(B)$ to B lies in C on the negative side of $B \cap C$. See Figure 1.1.

Remark 1.11: Said another way, $\mathcal{T}'$ corresponds to those parameters such that l is the real length of a shortest element of G , d is the real distance between B and a nearest translate, and $-l/2 < r \leq l/2$. In what follows, it is essential to remember that an element α of $\mathcal{P}'$ corresponds not only to a group G , but a group with two special generators. When $\alpha \in \mathcal{T}'$, then two (i.e. l and d) of α 's six real parameters correspond to invariants of $\{G, f, w\}$.

We are only interested in the subset of $\mathcal{T}'$ corresponding to parameters α with $d \leq \ln(3)$. The following two propositions imply this subset of $\mathcal{T}'$ lives in a compact subset of $\mathcal{P}'$.

Proposition 1.12: All closed geodesics of length less than 0.0979 in all hyperbolic 3-manifolds have embedded solid tube neighborhoods of radius $\ln 3/2$.

Proof: In [M1] it is proven that a geodesic of length $x + iy$ has an embedded solid-tube neighborhood of radius $r(x + iy)$ satisfying

$$\sinh^2(r(x + iy)) = \max_{n \in \mathbf{Z}_+} \frac{1}{2} \left(\frac{\sqrt{1 - 2k(x, y, n)}}{k(x, y, n)} - 1 \right) \text{ where } k(x, y, n) = \cosh(nx) - \cos(ny).$$

Of course, we restrict to $x + iy$ values which produce positive radii $r(x + iy)$ by means of this formula. It is easy to compute that for a given $x + iy$ we need to have n for which $0 < k(x, y, n) < -1 + \sqrt{2}$ to produce a positive radius tube by this method.

The function $\frac{1}{2} \left(\frac{\sqrt{1 - 2k}}{k} - 1 \right)$ is decreasing on the interval $(0, -1 + \sqrt{2})$. It is therefore easy to solve for the range of k values that produce radii r greater than $\ln 3/2$. In fact, positive k less than 0.3397 work.

Thus, to complete the proof of this proposition, we need to show that when a geodesic has real length x less than 0.0979, that for all angles y there exists a positive integer n for which $k(x, y, n)$ is less than 0.3397. Because $\cosh$ is an increasing function, we can restrict our analysis to $x = 0.0979$. Thus, we need only show that given any angle y , we can find a positive integer n such that $\cosh(n \cdot 0.0979) - \cos(ny) < 0.3397$. When $n > 8$ we can compute that $\cosh(n \cdot 0.0979) - \cos(ny) > 0.3397$, and we therefore restrict to positive integers $n \leq 8$.

We now consider angles y . Because $\cos$ is an even function, we need only consider $y \in [0, \pi]$. We will cover $[0, \pi]$ by 11 overlapping closed sub-intervals σ_i each of which has an associated positive integer n_i for which $\cosh(n_i \cdot 0.0979) - \cos(n_i y) < 0.3397$ is true for all $y \in \sigma_i$.

$$\sigma_0 = [0.000, 0.843] \quad n_0 = 1$$

$$\sigma_1 = [0.835, 0.960] \quad n_1 = 7$$

$$\sigma_2 = [0.951, 1.143] \quad n_2 = 6$$

$$\sigma_3 = [1.123, 1.391] \quad n_3 = 5$$

$$\sigma_4 = [1.386, 1.755] \quad n_4 = 4$$

$$\sigma_5 = [1.733, 1.858] \quad n_5 = 7$$

$$\sigma_6 = [1.832, 2.357] \quad n_6 = 3$$

$$\sigma_7 = [2.334, 2.3792] \quad n_7 = 8$$

$$\sigma_8 = [2.3789, 2.647] \quad n_8 = 5$$

$$\sigma_9 = [2.630, 2.755] \quad n_9 = 7$$

$$\sigma_{10} = [2.730, \pi] \quad n_{10} = 2$$

■

Proposition 1.13: If the *shortest* geodesic in a closed hyperbolic 3-manifold has length greater than or equal to 1.29, then it has an embedded solid tube neighborhood of radius $\ln 3/2$.

Proof: Consider the following folklore result: The *shortest* geodesic in a closed hyperbolic 3-manifold has an embedded solid tube neighborhood of radius $l/4$ where l is the real length of the shortest geodesic. The proof is simple: Expand a solid tube around the shortest geodesic, if it hits itself before a radius of $l/4$ then we will construct a loop of length less than l , a contradiction to “shortestness.” Drop the two obvious perpendiculars from the hitting point down to the core geodesic. Consider the following loop— down one perpendicular, follow the shorter direction on the core geodesic, up the other perpendicular. This non-trivial loop has length less than $l/4 + l/2 + l/4 < l$.

We now improve on this loop. Replace the first half of the journey by the hypotenuse of the right triangle formed by the first perpendicular and the first half of the shorter arc

along the core geodesic. Replace the second half of the journey by the hypotenuse of the right triangle formed by the second perpendicular and the second half of the shorter arc along the core geodesic. Using the hyperbolic Pythagorean Theorem (see [F]) $\cosh c = (\cosh a)(\cosh b)$ with $a = \ln 3/2$ and $b = l/4$ we get that the length of the constructed loop is $2 \cosh^{-1}(\cosh(\ln 3/2)(\cosh(l/4)))$ and this is less than l when $l > 1.29$, by a calculation and the fact that $2 \cosh^{-1}(\cosh(\ln 3/2)(\cosh(l/4))) - l$ is a decreasing function of l .

In fact, we can solve explicitly for the value of l at which

$$2 \cosh^{-1}(\cosh(\ln 3/2)(\cosh(l/4))) - l = 0.$$

Noting that $\cosh(\ln 3/2) = \frac{2}{\sqrt{3}}$ we get $\frac{2}{\sqrt{3}}(\cosh(l/4)) = \cosh(l/2)$. Using a half-angle formula for $\cosh(l/2)$ we get $\frac{2}{\sqrt{3}}(\cosh(l/4)) = 2 \cosh^2(l/4) - 1$. Setting $x = \cosh^2(l/4)$ we get the quadratic $\frac{2}{\sqrt{3}}x = 2x^2 - 1$. Solving and substituting, we get $l = 1.289784...$ ■

Definition 1.14: Let $\mathcal{P} \subset \mathcal{P}'$ be those parameters $\alpha = (l + it, d + ib, r + ia)$ such that

- a) $-\pi \leq t \leq 0$
- b) $0 \leq r \leq l/2$
- c) $0.0978 \leq l \leq 1.29$
- d) $l/2 \leq d \leq \ln(3)$

Define $\mathcal{T} = \mathcal{T}' \cap \mathcal{P}$.

Lemma 1.15: If $\alpha = (l + it, d + ib, r + ia) \in \mathcal{T}'$ has $d \leq \ln(3)$ and corresponds to a 2-generator group $\{G_\alpha, f_\alpha, w_\alpha\}$, then there exists a parameter $\beta \in \mathcal{T}$ with associated group $\{G_\beta, f_\beta, w_\beta\}$ such that G_β is conjugate to G_α .

Proof: $d < l/2$ is eliminated from consideration by the first paragraph of the proof of Proposition 1.13, and the definition of $\mathcal{T}'$. If $d \leq \ln(3)$, then $0.0978 \leq l \leq 1.29$ by Proposition 1.12. If for the triple $\{G, f, w\}$ we have $-l/2 < r < 0$, then the triple $\{G, f, w^{-1}\}$ is conjugate to an element of $\mathcal{T}$ whose new r -parameter is $-r$. Thus we can assume that b), c), and d) hold for the relevant $\{G, f, w\}$.

This leaves property a). Conjugating G by a reflection in the geodesic plane spanned by B and C changes the t -parameter to $-t \pmod{2\pi}$. The effect on b and a is irrelevant. ■

By [G; Lemma 5.9] a closed orientable hyperbolic 3-manifold N satisfies the insulator condition provided that $\text{tuberadius}(\delta) > \ln(3)/2$ for some geodesic $\delta \subset N$. Thus we are led to ask

Question 1.16: List all closed orientable hyperbolic 3-manifolds N possessing a shortest geodesic δ such that $\text{tuberadius}(\delta) \leq \ln(3)/2$.

Remarks 1.17: i) Using a J. Weeks-modified version of Snappea it was known experimentally that any shortest geodesic in Vol3 has a .415... tube (see [G]). Conjecturally, up to isometry, there are a total of six manifolds in the list answering Question 1.16 (see Theorem 1.30 and Remark 1.31 iii, and Theorem 4.xx).

ii) If a shortest geodesic δ in N satisfies $\text{tuberadius}(\delta) \leq \ln(3)/2$, then N can be expressed as $\mathbf{H}^3/\Gamma$ where a lift of δ is the geodesic B , and C is an ortholine between B

and a nearest Γ -translate. Thus N gives rise to an element $\alpha \in \mathcal{T}$. In fact N may give rise to finitely many different elements of $\mathcal{T}$. Thus we need to investigate.

Question 1.18: Name all parameters $\alpha = (l + it, d + ib, r + ia) \in \mathcal{T}$.

We now describe our method of (partially) answering Question 1.18. There is a technical point to mention: starting with Definition 1.22, we will work in the space $\mathcal{W} \supset \exp(\mathcal{P})$, but for now we will describe the results in terms of the unexponentiated space $\mathcal{P}$.

We will partition $\mathcal{P}$ into about one billion regions $\{\mathcal{P}_i\}$ and show that $\mathcal{T}$ is disjoint from all but seven small such regions. Suppose that $\mathcal{P}_i$ is a region of this partition and $\alpha \in \mathcal{P}_i$. Let h be a word in the letters f, w and their inverses. Associated to the parameter $\alpha = (l_\alpha + it_\alpha, d_\alpha + ib_\alpha, r_\alpha + ia_\alpha)$ there are the group elements f_α, w_α and hence h_α . Suppose that $h_\alpha \neq f_\alpha^m$. We ask

- a) Is $\text{Relength}(h_\alpha) < \text{Relength}(f_\alpha) = l_\alpha$?
- b) Is $\text{Redistance}(h_\alpha(B), B) < \text{Redistance}(w_\alpha(B), B) = d_\alpha$?

If either a) or b) is true, then $\alpha \notin \mathcal{T}$.

Now let $\beta \in \mathcal{P}_i$, with f_β, w_β , and h_β the associated hyperbolic isometries. If say a) is true for α then so is the statement $\text{Relength}(h_\beta) < \text{Relength}(f_\beta) = l_\beta$ for β sufficiently close to α . Thus we can show that $\mathcal{T} \cap \mathcal{P}_i = \emptyset$ if we can find an α for which say statement a) is true, and then use first-order Taylor approximation (with error/remainder term) to show that the corresponding statement holds for all $\beta \in \mathcal{P}_i$.

Definition 1.19: A word h in w, f, w^{-1}, f^{-1} for which statement a) (resp. b)) holds (non-trivially) for each $\beta \in \mathcal{P}_i$ is called a *killer word* for $\mathcal{P}_i$ with respect to contradiction a) (resp. b)).

Summary 1.20: With seven exceptions, to each of the approximately one billion regions partitioning $\mathcal{P}$, we will associate a killerword and a contradiction.

Remark 1.21: Computers are well suited for partitioning a region such as $\mathcal{P}$ into many sub-regions $\{\mathcal{P}_i\}$, and finding a killerword h_i which eliminates $\alpha_i \in \mathcal{P}_i$ due to contradiction C_i . Depending on the contradiction, we find computable expressions for approximations of the values of $\text{Relength}(h_\beta)$ or $\text{Redistance}(h_\beta(B), B)$ and thus use the computer to eliminate all of $\mathcal{P}_i$.

There are a number of difficulties in executing this procedure. First, a uniform mesh of the partition would yield far too many sub-regions to be handled by computer. In fact with 6 real parameters, refining a given mesh by a factor of 10 would change the partition size by a factor of 10^6 . Our method for refining the parameter space and the way the computer keeps track of the refinements are discussed briefly in Remark 1.27 and in more detail in Chapter 5.

A second difficulty is finding the killerwords. In practice, most of the parameter space is eliminated by killerwords of length less than 7, but a number of spots need killerwords of length 10 and a few regions need killerwords of length 35. A brute force enumeration and testing of the various words would take far too long. Note that there are more than 70,000 words of length 10 and 4×3^{29} words of length 30. Techniques for finding killer words can be found in [Txxx].

Finally, there is the issue of rigor. The main difficulty in making the plan work rigorously is that we need to bound the difference between what the computer thinks a value is and what the value actually is. In particular we need to control roundoff error, which becomes quite significant when one does a large number of multiplications, e.g. in the computation of $\text{length}(h_\alpha)$ when h is a 35 letter word. Another issue is to make sure that h_β is bounded away from f_β^m , and in particular bounded away from id , when computing say $\text{Relength}(h_\beta)$. A large portion of this paper is devoted to addressing these issues. See Remark 1.30 for a more detailed discussion.

Definition 1.22: Let

$$\mathcal{W} = \{(x_0, x_1, x_2, x_3, x_4, x_5) : |x_i| \leq 4 \times 2^{(5-i)/6} \text{ for } i = 0, 1, 2, 3, 4, 5\}$$

$$\supset \exp(\mathcal{P}) = \{(x_0, x_1, x_2, x_3, x_4, x_5) \mid \\ x_0 + ix_3 = \exp(e), x_1 + ix_4 = \exp(f), x_2 + ix_5 = \exp(g) \text{ where } (e, f, g) \in \mathcal{P}\}$$

and let

$$\mathcal{S} = \exp(\mathcal{T}).$$

Also, let

$$L' = \exp(L) = \exp(l + it), \quad D' = \exp(D) = \exp(d + ib), \quad R' = \exp(R) = \exp(r + ia).$$

Remarks 1.23: i) We work with $\mathcal{W}$ instead of $\exp(\mathcal{P})$ because we want our initial region to be a (6-dimensional) box that is easily sub-divided. This has the side-effect that certain sub-boxes $\mathcal{W}_i$ of $\mathcal{W}$ will be eliminated because they are outside of $\exp(\mathcal{P})$ rather than by the analogues of conditions a) and b) above. The entire collection of conditions is given in Section 5.

ii) All the ideas expressed in 1.18-1.21 will be carried out in the parameter space $\mathcal{W}$ rather than the space $\mathcal{P}$. That is mainly because of Lemmas 1.24 - 1.26 which demonstrate that while working in $\mathcal{W}$ one need only understand the basic arithmetic operations $+$, $-$, $\times$, $/$, $\sqrt{}$.

iii) The reason for choosing the co-ordinates of $\mathcal{W}$ so that $L' = x_0 + ix_3$, $D' = x_1 + ix_4$, $R' = x_2 + ix_5$ was to gain a mild computer advantage.

Lemma 1.24: If $(L', D', R') \in \mathcal{W}$ and f, w are the generators of the associated group G then

a)

$$\text{Matrix}[f] = \begin{pmatrix} \sqrt{L'} & 0 \\ 0 & 1/\sqrt{L'} \end{pmatrix}$$

b)

$$\text{Matrix}[w] = \begin{pmatrix} \sqrt{R'} * ch & sh * \sqrt{R'} \\ sh/\sqrt{R'} & ch/\sqrt{R'} \end{pmatrix}$$

$$\text{where } ch = (\sqrt{D'} + 1/\sqrt{D'})/2 \quad \text{and} \quad sh = (\sqrt{D'} - 1/\sqrt{D'})/2$$

Proof: a) By our set-up we have that the (oriented) axis of f is B . Following the proof of Lemma 1.3,

$$\text{Matrix}[f] = \begin{pmatrix} p & 0 \\ 0 & 1/p \end{pmatrix}$$

where $p = \exp(\text{length}(f)/2) = \sqrt{\exp(\text{length}(f))} = \sqrt{\exp(L)} = \sqrt{L'}$

b) $w = \beta \circ \alpha$ where β is translation of distance R along B and α is translation of distance D along C . Thus,

$$\text{Matrix}[\beta] = \begin{pmatrix} \sqrt{R'} & 0 \\ 0 & 1/\sqrt{R'} \end{pmatrix}$$

and $\text{Matrix}[\alpha]$ can be computed to be

$$\begin{pmatrix} \cosh(D/2) & \sinh(D/2) \\ \sinh(D/2) & \cosh(D/2) \end{pmatrix}.$$

But $\cosh(D/2) = (\exp(D/2) + \exp(-D/2))/2 = (\sqrt{D'} + 1/\sqrt{D'})/2 = ch$ and similarly for sh . Thus,

$$\text{Matrix}[\alpha] = \begin{pmatrix} ch & sh \\ sh & ch \end{pmatrix}$$

and b) follows by matrix multiplication. ■

Lemma 1.25: If $h \in \text{Isom}(\mathbf{H}^3)$ is represented by the matrix

$$A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{PSL}(2, \mathbf{C}),$$

then

- a) $\exp(\text{Relength}(h)) = |\text{trace}(A) \pm \sqrt{(\text{trace}(A)/2)^2 - 1}|^2$
- b) $\exp(\text{Redistance}(h(B), B)) = |\text{orthotrace}(A) \pm \sqrt{(\text{orthotrace}(A)/2)^2 - 1}|$
 where $\text{orthotrace}(A) = ad + bc$.

Here the $+$, $-$ produce reciprocal values for $\exp(\text{Relength}(h))$, and we take the one producing the larger value, unless the value is 1, in which case there is no choice.

Proof: Because $\cosh(x) = (\exp(x) + \exp(-x))/2$ it is easy to compute that $\cosh^{-1}(x) = \log(x \pm \sqrt{x^2 - 1})$. Of course, $x - \sqrt{x^2 - 1}$ and $x + \sqrt{x^2 - 1}$ are inverses, which corresponds to the fact that $\cosh^{-1}(x)$ for $x \neq 1$ consists of values differing by a factor of -1 .

- a) $\exp(\text{Relength}(h)) = |\exp(\text{length}(h))| = |\exp(2\text{Arccosh}(\text{trace}(A)/2))| = |(\text{trace}(A)/2) \pm \sqrt{(\text{trace}(A)/2)^2 - 1}|^2$ where the second equality follows from Lemma 1.2.
- b) $\exp(\text{Redistance}(h(B), B)) = |\exp(\text{distance}(h(B), B))| = |\exp(\text{Arccosh}(ad + bc))| = |(ad + bc) \pm \sqrt{(ad + bc)^2 - 1}|$ where the second equality follows from Lemma 1.7. ■

Remarks 1.26: i) It follows from Lemma 1.25 that if h is a word in f, w and their inverses, then for any parameter value $\alpha \in \mathcal{W}$, $\exp(\text{Relength}(h_\alpha))$, and $\exp(\text{Redistance}(h_\alpha(B), B))$ can be computed using only the operations $+$, $-$, $\times$, $/$, $\sqrt{\cdot}$. ■

ii) During the course of the computer work needed to prove the main theorems, the parameter space $\mathcal{W}$ was decomposed into sub-boxes by computer via a recursive sub-division process: Given a sub-box that is being analyzed, either it can be handled, or it cannot. If it cannot be handled, it is sub-divided in half by a hyper-plane $\{x_i = c\}$ (where i runs through the various co-ordinate dimensions cyclically) and the two pieces are analyzed separately. And so on.

As such, a sub-box of $\mathcal{W}$ can be described by a sequence of 0's and 1's where 0 means "take the lesser x_i values" and 1 means "take the greater x_i values." Remarkably, for the decomposition of $\mathcal{W}$ into sub-boxes, all the sub-box descriptions could be neatly encoded into one tree (although in practice we found it preferable to use several trees to describe the entire decomposition). This is described in Chapter 5.

iii) In the following proposition, seven exceptional boxes are described as sequences of 0's and 1's. Four of the boxes— X_0, X_4, X_5, X_6 — are each the union of two abutting sub-boxes, $X_0 = X_{0a} \cup X_{0b}$ and so on. It is a pleasant exercise to work through the fact that they abut.

It is also a pleasant exercise to calculate by hand the co-ordinate ranges of the various sub-boxes. For example, the range of the last co-ordinate (i.e., x_5) of the sub-box

$$X_{6a} = 111000000001000111 \ 111111110101001111 \ 011111010111111111 \\ 110001001011000111 \ 0$$

is found by taking the 6th entry, the 12th, entry, the 18th entry and so on. These entries are 011111111111. The first entry (0) means take the lesser x_5 values, and produces the interval $[-4, 0]$. The second entry (1) means take the greater x_5 values, and produces the interval $[-2, 0]$. The third entry (1) produces $[-1, 0]$. Continuing, we see that X_{6a} has $-2^{-9} \leq x_5 = \text{Im}(R') \leq 0$. The other co-ordinates can be computed in the same fashion, although they must at the end be multiplied by the factor $2^{(5-i)/6}$ (see the definition of the initial box $\mathcal{W}$). The range of co-ordinate values is given for each of the seven boxes. Finally, two *quasi-relators* are given for each sub-box $X_0, X_1, \dots, X_6$.

Definition 1.27: A *quasi-relator* in a sub-box X of $\mathcal{W}$ is a word in f, w, f^{-1}, w^{-1} that is close to the identity throughout X and experimentally appears to be converging to the identity at some point in X . In particular, a quasi-relator rigorously has Relength less than that of f at all points in X .

Proposition 1.28: $S \cap (\mathcal{W} - \bigcup_{n=1, \dots, 7} X_n) = \emptyset$ where the X_n are the exceptional sub-boxes

$$X_{0a} = 001000110111110001 \ 101001010101011001 \ 011011010111101101 \\ 100001101101000111 \ 010001110101100101 \ 1101110111110100$$

$$X_{0b} = 001001110110110000 \ 101000010100011000 \ 011010010110101100 \\ 100000101100000110 \ 010000110100100100 \ 1101100111100100$$

$$X_0 = \begin{pmatrix} -0.840655162503 \dots \leq \operatorname{Re}(L') \leq -0.840600786360 \dots \\ -0.840642408899 \dots \leq \operatorname{Re}(D') \leq -0.840593965263 \dots \\ 0.999979499517 \dots \leq \operatorname{Re}(R') \leq 1.000022657890 \dots \\ -2.137267196028 \dots \leq \operatorname{Im}(L') \leq -2.137228746289 \dots \\ -2.137295441962 \dots \leq \operatorname{Im}(D') \leq -2.137226932315 \dots \\ -0.000061035156 \dots \leq \operatorname{Im}(R') \leq 0.000061035156 \dots \end{pmatrix}$$

$$000000111010110110 \ 1$$

$$X_5 = \begin{pmatrix} -1.379848991182 \dots \leq \operatorname{Re}(L') \leq -1.378108954623 \dots \\ -1.379674742433 \dots \leq \operatorname{Re}(D') \leq -1.376574349753 \dots \\ 0.999893182771 \dots \leq \operatorname{Re}(R') \leq 1.002655318635 \dots \\ -2.537067582893 \dots \leq \operatorname{Im}(L') \leq -2.534606799593 \dots \\ -2.536501152136 \dots \leq \operatorname{Im}(D') \leq -2.534308843448 \dots \\ -0.001953125000 \dots \leq \operatorname{Im}(R') \leq 0.001953125000 \dots \end{pmatrix}$$

2-generator 2-relator presentation $\langle f, w; r_1, r_2 \rangle$ is the group presentation of a Heegaard genus 2 closed orientable 3-manifold. ■

Remarks 1.31: i) In Chapter 3 it is proven rigorously that Vol3, the hyperbolic 3-manifold with the third smallest volume known, is the unique manifold associated with sub-box X_0 . As of this writing its not known if the other boxes have unique manifolds.

ii) Except for Vol3, Riley's program POINCARÉ was the first to show (experimentally) that there is a closed orientable (hyperbolic) 3-manifold associated to each box. It provided a group presentation, which presumably could have been shown to be those of the above.

iii) Experimental evidence suggests that the manifolds associated to X_5 and X_6 are isometric hyperbolic 3-manifolds, isometric to the Weeks census manifold $s479(-3, 1)$. Also experimentally, the manifold associated with X_2 is $s778(-3, 1)$ and the manifold associated with X_1 is $v2678(2, 1)$.

iv) Berge [Be] provides the explicit Heegaard genus 2 diagrams for each of the manifolds in Experimental Theorem 1.30, so that the dilligent reader can recover Dehn surgery descriptions of these manifolds.

Remark 1.32: It might be best to say that the list of killerwords and contradictions used to prove Proposition 1.28 was generated in an artistic rather than systematic mathematical way. Nevertheless, to have a rigorous mathematical proof one need only prove that these words work.

Remark 1.33: Recall that we use first-order Taylor approximations (with Remainder term) which we denote *AffApprox's* to show that a killer word which eliminates a point $x \in \mathcal{W}_i$ eliminates all of $\mathcal{W}_i$. In setting up a Taylor approximation system we avoided a considerable amount of calculation by using the parameter space $\mathcal{W}$ instead of working with $\mathcal{P}$.

In the parameter space $\mathcal{W}$, all functions analyzed via Taylor approximations are built up from the operations $+$, $-$, $\times$, $/$, $\sqrt{}$. We prove combination formulas for these functions, which show how the Taylor approximations (including the Remainder term) change when one of these operations is applied to two AffApprox's. This is carried out in Chapter 6.

To ensure that all of our computer calculations are rigorous, we use a round-off error analysis. Typically, this is done by using interval arithmetic on floating-point numbers. This is too slow for our purposes, and so we introduce round-off error at the level of AffApprox's and incorporate the round-off error into the Remainder term. This also requires developing round-off error for complex numbers. This is all done in Chapters 7 and 8.

Chapter 2: The Corona Insulator Family

The upshot of Proposition 1.28 is that if a closed orientable hyperbolic 3-manifold has a shortest geodesic which does not have an embedded $\ln 3/2$ tube then the parameters for its associated 2-generator subgroup(s) (G, f, w) must be in one of the sub-boxes $X_0, X_1, \dots, X_6$ listed in that proposition. Nonetheless—as we shall see in this Chapter and the next—such manifolds have non-coalescable insulator families about their shortest geodesics. However, they might not be Dirichlet insulator families.

In this Chapter, we describe a new insulator family $\{\kappa_{ij}\}$ called the Corona insulator, and we describe a condition sufficient for this family to be non-coalescable—a condition which is weaker than the tuberadius(δ) $> \ln(3)/2$ sufficient condition for the Dirichlet insulator family.

The reason Dirichlet insulator families for geodesics with solid tubes of radius greater than $\ln 3/2$ are non-coalescable is that the amount of visual angle taken up by the various insulators is less than 120 degrees, and thus there is no chance for tri-linking to occur. The visual angle (measured at one axis) for a member of the Dirichlet insulator family associated to two axes depends only on the real distance between the two axes.

In contrast, the visual angle for a member of the Corona insulator family associated to two axes depends on the (complex) distance between the two axes. We now give this function, $\mathcal{C}$, and name it the *Corona* function. After that we give a precise definition of the visual angle function, and prove that the Corona function is the proper visual angle function for the Corona insulator family.

Definition 2.1: Let $\mathcal{C} : (0, \infty) \times S^1 \rightarrow \mathbf{R}$ be defined by

$$\mathcal{C}(u, v) = |\operatorname{Im}(\operatorname{Arccosh}(1 - \frac{4}{1 \pm \cosh(u + iv)}))|$$

where $\pm$ is positive for $-\pi/2 \leq v \leq \pi/2$ and negative otherwise.

In the following definition, it is helpful to imagine the geodesic σ as being the z -axis in the upper-half-space model of $\mathbf{H}^3$.

Figure 2.1

Definition 2.2: If $\sigma \subset \mathbf{H}^3$ is a geodesic, then $S_\infty^2 - \partial\sigma$ is parametrized by $S^1 \times \mathbf{R}$ (these are sometimes called Steiner circles) where each $x \times \mathbf{R}$ lies in the ideal boundary of a hyperbolic halfplane bounded by σ , two such lines $x \times \mathbf{R}$, $y \times \mathbf{R}$ are at distance θ in the S^1 factor if they meet at $\partial\sigma$ at angle θ . If $R \subset S_\infty^2 - \partial\sigma$, then define $\text{visualangle}_\sigma(R) = \theta \in [0, 2\pi]$, where $\theta = \inf\{\theta_2 - \theta_1 \bmod 2\pi \mid R \subset [\theta_1, \theta_2] \times \mathbf{R}\}$. The possible choice of 0 or 2π is made in the obvious manner.

Proposition 2.3: Let δ_i, δ_j be disjoint oriented geodesics in $\mathbf{H}^3$. Then there exists a smooth simple closed curve κ_{ij} in S_∞^2 separating $\partial\delta_i$ from $\partial\delta_j$ such that for $k \in \{i, j\}$, $\text{visualangle}_{\delta_k}(\kappa_{ij}) = \mathcal{C}(\text{distance}(\delta_i, \delta_j))$.

Proof: Let P be the orthocurve from δ_i to δ_j . Consider the half-plane with boundary δ_i determined by δ_i and P , and the half-plane with boundary δ_j determined by δ_j and P . Allow these half-planes to expand into *solid angles* at the same rate. (A solid angle is a closed set in $B^3 = \mathbf{H}^3 \cup S_\infty^2$ bounded by two hyperbolic halfplanes which meet along a common geodesic.) At first, the four half-planes that bound these solid angles intersect in $\mathbf{H}^3$, but at some angle θ these half-planes intersect only at infinity (that is, in S_∞^2). By reasons of symmetry they intersect in two or four points (four points of intersection occur when $\text{Im}(\text{distance}(\delta_i, \delta_j))$ is $\pi/2$ or $3\pi/2$).

Let S_i, S_j be the solid angles which exist at angle θ . Let $T_k = S_k \cap S_\infty^2$ for $k \in \{i, j\}$. Let κ_{ij} be a simple closed curve in $T_i \cap T_j$ which separates $\partial\delta_i$ from $\partial\delta_j$. By construction, for $k \in \{i, j\}$ $\text{visualangle}_{\delta_k}(\kappa_{ij}) = \theta$. See Figure 2.2.

To complete the proof of the Proposition, we now show that $\theta = \mathcal{C}(\text{distance}(\delta_i, \delta_j))$. To do this, we use hyperbolic trigonometry on a degenerate right-angled hexagon in $\mathbf{H}^3$. Following [F], a degenerate right-angled hexagon is a 5-tuple of oriented geodesics $S_1, \dots, S_5$ in $\mathbf{H}^3$ such that S_i is orthogonal to S_{i+1} and S_1 and S_5 limit at a common point S_0 at infinity. These oriented geodesics give rise to complex numbers $\sigma_0, \sigma_2, \sigma_3, \sigma_4$. $\sigma_0 = 0$ if the axes S_1 and S_5 either both point into S_0 or both point out of S_0 . Otherwise $\sigma_0 = \pi i$. For $k \in \{2, 3, 4\}$ $\sigma_k = e$ if an e -translation of the oriented geodesic S_k takes the oriented geodesic S_{k-1} to the oriented geodesic S_{k+1} . By [F; pg. 83] we have the following Hyperbolic Law of Cosines.

$$\cosh(\sigma_0) = \cosh(\sigma_2) \cosh(\sigma_4) + \sinh(\sigma_2) \sinh(\sigma_4) \cosh(\sigma_3).$$

We work in the upper-half-space model of hyperbolic 3-space, and normalize so that the ortholine from δ_j to δ_i is B (thus δ_i intersects B above δ_j), while the oriented axis δ_i is C . B will be S_3 , while the oriented geodesics δ_i and δ_j will be S_2 and S_4 , respectively.

Of course, $u + iv = \text{distance}(\delta_i, \delta_j)$. If $-\pi/2 \leq v \leq 0$ then the intersection points at infinity occur in the second quadrant and the fourth quadrant (see Figure 2.3a). For convenience, we work with the point in the second quadrant and send (unique) perpendiculars from it to the geodesics δ_i and δ_j . The perpendicular to δ_i will be oriented towards δ_i and then denoted S_1 , while the perpendicular to δ_j will be oriented away from δ_j and then denoted S_5 . The intersection point at infinity (in the second quadrant) is S_0 .

This is the proper set-up for applying the (degenerate) Hyperbolic Law of Cosines (see Figure 2.3b). Note that $\sigma_3 = -(u + iv)$, and $\sigma_0 = i\pi$. By symmetry $\sigma_2 = \sigma_4 = (\alpha + i\beta)/2$ where $(\alpha + i\beta)/2$ is $\text{distance}(S_1, S_3)$. Plugging into the Law of Cosines, using a half-angle

formula ($\cosh(2z) = 2 \cosh^2(z) - 1 = 2 \sinh^2(z) + 1$), solving for $\cosh(\alpha + i\beta)$, and taking the Arccosh, we get the desired result. Note that the visual angle in this set-up is $-\beta$, thus necessitating taking the absolute value.

When $0 \leq v \leq \pi/2$ our 2 intersection points occur in the first and third quadrants, and we carry out the same procedure. This time S_2 and S_4 are traversed in the direction opposite to their orientations (the attendant changes in sign drop out though). In this case, the visual angle is β .

The cases $-\pi \leq v \leq -\pi/2$ and $\pi/2 \leq v \leq \pi$ reduce to the previous cases after adding or subtracting π . The formula in Definition 2.1 is then obtained after noting that $\cosh(z \pm i\pi) = -\cosh(z)$. ■

Definition 2.4: Let δ be a simple closed geodesic in the closed orientable hyperbolic 3-manifold N . Let $\{\delta_i\}_{i \geq 0}$ be the lifts of δ to $\mathbf{H}^3$. For each $\pi_1(N)$ -orbit of unordered pairs (δ_i, δ_j) choose a representative where $i = 0$. If $\text{Redistance}(\delta_0, \delta_i) \leq \ln(3)/2$, then let κ_{0j} be a smooth simple closed curve in S^2 separating $\partial\delta_0$ from $\partial\delta_j$ such that for $k \in \{0, j\}$, $\text{visualangle}_{\delta_k}(\kappa_{0j}) = C(\text{distance}(\delta_0, \delta_j))$. If $\text{Redistance}(\delta_0, \delta_i) > \ln(3)/2$, then let κ_{0j} be the Dirichlet insulator, i.e. the boundary of the geodesic plane orthogonally bisecting the orthocurve between δ_0, δ_j .

In either case, extend the collection $\pi_1(N)$ -equivariantly to a family $\{\kappa_{ij}\}$ defined for all i, j . This is the Corona family for δ .

Figure 2.3

Lemma 2.5: The Corona family $\{\kappa_{ij}\}_{S_0}$ is

- i) an insulator family for δ
- ii) noncoalescable if $\max\{\mathcal{C}(\delta_0, \delta_j) \mid j > 0\} < 2\pi/3$.

Proof: We check that $\{\kappa_{ij}\}$ satisfies the various conditions of Definitions 0.4-0.5 of [G].

i) By construction, κ_{ij} separates $\partial\delta_i$ from $\partial\delta_j$ and $\{\kappa_{ij}\}$ is $\pi_1(N)$ -equivariant. Because for $k \in \{i, j\}$, $\delta_k - \text{visualangle}(\kappa_{ij}) < \pi$, $\{\kappa_{ij}\}$ satisfies the convexity condition.

Modulo the natural action of $\pi_1(N)$ on κ_{ij} , there are only finitely many insulators κ_{ij} which are not Dirichlet insulators. Therefore, for fixed i , there exist only finitely many κ_{ij} such that $\text{diam}(\kappa_{ij}) > \epsilon$. This establishes local finiteness. ■

- ii) No trilinging follows immediately from ii). ■

Definition 2.6: If δ is a simple closed geodesic in the hyperbolic 3-manifold N , define $\text{maxcorona}(\delta) = \max\{\mathcal{C}(\delta_0, \delta_j) \mid j > 0\}$

Remark 2.7: a) It seems possible that the Dirichlet insulator family associated to the geodesic $\delta \in N$ may be non-coalescable, while the Corona insulator family is coalescable and conversely.

b) If $\text{tuberadius}(\delta) > \ln(3)/2$, then both the Dirichlet insulator and Corona insulator families coincide and by Lemma 5.9 of [G] they are non-coalescable.

Proposition 2.8: Let δ be a shortest geodesic in the closed orientable hyperbolic 3-manifold N . Then either the Corona insulator family is noncoalescable or there exists a 2-generator subgroup G of $\pi_1(N)$ with generators f, w such that the parameter associated to $\{G, f, w\}$ lies in the sub-box $X_0 = X_{0a} \cup X_{0b} \subset \mathcal{W}$.

Proof: Let δ be a shortest geodesic in N , a closed orientable hyperbolic 3-manifold. By Corollary 1.29 and Lemma 2.5 either δ has a non-coalescable insulator family or $\text{length}(\delta)$ lies in $\mathcal{L}(X_k)$ for some $k \in \{0, 1, \dots, 6\}$ and $\text{maxcorona}(\delta) \geq 2\pi/3$. Let G be a 2-parameter subgroup of $\pi_1(N)$ generated by f and g , where f corresponds to δ and has axis B and g maximizes $\mathcal{C}(g(B), B)$. We will show that if $\mathcal{C}(g(B), B) \geq 2\pi/3$, then the parameter associated to $\{G, f, g\}$ lies in the sub-box X_0 .

In fact we will show that if $\{G, f, g\}$ is any torsion-free subgroup of $\text{Isom}(\mathbf{H}^3)$ where f is a length-minimizing loxodromic element with axis B and g maximizes $\mathcal{C}(g(B), B)$ where $\mathcal{C}(g(B), B) \geq 2\pi/3$, then the parameter $\beta = (L_\beta, D_\beta, R_\beta) \in \exp^{-1}(X_0)$.

It follows as in the first paragraph that $L_\beta \in \mathcal{L}(X_k)$ for some $k \in \{0, 1, 2, 3, 4, 5, 6\}$. Also D_β is subject to nontrivial constraint. For example if $L_\beta \in \mathcal{L}(X_1)$, then D_β must lie in the decorated region of Figure 2.4, because $\text{Redistance}(g(B), B) \geq \min_d(X_k) > 1.059$ where $\min_d(X_k)$ is the minimal d value in X_k . In fact the disjointness of the $\mathcal{L}(X_k)$'s implies that if $\beta \in S \cap X_k$, then $\text{tuberadius}(\delta) \geq \min_d(X_k)/2$, where δ corresponds to the element f . Finally $\mathcal{C}(g(B), B) \geq 2\pi/3$ implies that D_β cannot lie in the decorated region of Figure 2.4.

Our proof is now similar to the proof of Proposition 1.28. We partition the initial box $\mathcal{W}$ into sub-boxes $\mathcal{W}_i$ and eliminate $\mathcal{W}_i$ if any of the following conditions hold (for clarity, the conditions have been translated into “pre-exponentiated” form).

- There exists no $\beta \in \mathcal{W}_i$ such that $\text{length}(f_\beta) \in \mathcal{L}(X_k)$.
- $\mathcal{W}_i$ has some L values in $\mathcal{L}(X_k)$ but there exists no $\beta \in \mathcal{W}_i$ such that distance $(w_\beta(B), B) \in \text{decorated region}$ for that k .

- c) There exists a killerword h in f, w, f^{-1}, w^{-1} , such that $\text{Relength}(h_\beta) < \text{Relength}(f_\beta)$ and $h_\beta \neq \text{id}$ for all $\beta \in \mathcal{W}_i$.
- d) There exists a killer word h in f, w, f^{-1}, w^{-1} such that

$$\mathcal{C}(\text{distance}(h_\beta(B), B)) > \mathcal{C}(\text{distance}(w_\beta(B), B))$$

and $h_\beta(B) \neq B$ for all $\beta \in \mathcal{W}_i$.

We have two files that contain the decomposition of $\mathcal{W}$ into sub-boxes and associated conditions/(killer words). The program *fudging* checks that these files do indeed eliminate all of $\mathcal{W} - X_0$. *Fudging* analyzes the cases $k = 1, \dots, 6$ all at once. ■

Remarks 2.9: i) Note that in practice the proof of Proposition 2.8 requires working in a considerably smaller parameter space than that of Proposition 1.28. Condition a) implies that the parameter space is “ $(2 + \epsilon)$ -complex dimensional” and condition b) implies that one of these parameters is greatly constrained. This suggests why it took so much longer to come up with the partition and the associated killer words for Proposition 1.28. In fact, it took roughly 1500 CPU days to find the partition and the associated killer words for Proposition 1.28, versus roughly 2 CPU days for Proposition 2.8. Here, the term “CPU day” refers to 24 hours of running an SGI Indigo 2 workstation with an R4400 chip, and the estimate of 1500 CPU days refers to 15 to 20 such machines running 80 to 90 percent of the time for 3 to 4 months.

ii) We took pains to make *fudging* as similar to *verify* as we could, thereby lessening the amount of analysis needed to show the veracity of *fudging*. Appendix 2 contains those sections of *fudging* that differ from corresponding sections of *verify*.

iii) When working with exponentiated co-ordinates (that is, in $\mathcal{W}$ rather than $\mathcal{P}$) the Corona function changes as follows. Let $X = \exp(\alpha + i\beta)$ and $U = \exp(u + iv)$, then the Corona function formula

$$\cosh(\alpha + i\beta) = 1 - \frac{4}{1 + \cosh(u + iv)}$$

becomes

$$\frac{X + X^{-1}}{2} = 1 - \frac{4}{1 + (U + U^{-1})/2}$$

It is a pleasant exercise to solve this, and we find that

$$X = \frac{(U^2 - 6U + 1) \pm 4(U - 1)\sqrt{-U}}{(U + 1)^2}$$

the two answers so gotten are reciprocals, which means their associated arguments are opposites. In *fudging*, the exponentiated version of the Corona function is the function *horizon(ortho)*, which takes in $U = \text{ortho}$ and computes the associated X value. β , the argument of X , is implicitly gotten in the function *larger-angle*.

iv) It is possible that by working purely in the context of the Corona function, rather than first working with Redistance and attempting to prove Proposition 1.28, the computer proof can be simplified. We started this project with the naive idea that perhaps Vol3 was

the only manifold whose shortest geodesic did not have a $\ln(3)/2$ tube. The remarkable fact that this naive idea is almost correct accounts for the fact that a proof of Theorem 0.2 can be obtained with only the mild extra effort detailed in this chapter and the next.

For $0 \leq v \leq \pi/2$ $\mathcal{C}(u, v) = \beta$ where β satisfies

$$\cosh(\alpha + i\beta) = 1 - \frac{4}{1 + \cosh(u + iv)}.$$

For $-\pi/2 \leq v \leq 0$ $\mathcal{C}(u, v) = -\beta$ where β satisfies

$$\cosh(\alpha + i\beta) = 1 - \frac{4}{1 + \cosh(u + iv)}.$$

For $\pi/2 \leq v \leq \pi$ $\mathcal{C}(u, v) = -\beta$ where β satisfies

$$\cosh(\alpha + i\beta) = 1 - \frac{4}{1 + \cosh(u + i(v - \pi))}.$$

For $-\pi \leq v \leq -\pi/2$ $\mathcal{C}(u, v) = \beta$ where β satisfies

$$\cosh(\alpha + i\beta) = 1 - \frac{4}{1 + \cosh(u + i(v + \pi))}.$$

In all of these cases, we normalize the sign of β by requiring that α be positive.

Lemma 2.10: i) if $h = wFwfWfwf$ then $\text{Relength}(h_\alpha) < \text{Relength}(f_\alpha)$ for all parameters α in $\exp^{-1}(X_0)$

ii) if $h_2 = wFwfWfwFw$ then $\text{Relength}(h_\alpha) < \text{Relength}(f_\alpha)$ for all parameters α in $\exp^{-1}(X_0)$

iii) $|R| < |L/2|$ throughout $\exp^{-1}(X_0)$.

Proof: This easy calculation was carried out by *verify*. ■

Chapter 3: Vol3

The two main results of this chapter are

Proposition 3.1: If N is a closed orientable hyperbolic 3-manifold, then either N is Vol3, the third smallest known closed orientable hyperbolic 3-manifold, or $\text{maxcorona}(\delta) < 2\pi/3$ for δ a shortest geodesic in N .

Proposition 3.2: Any shortest geodesic in Vol3 satisfies the insulator condition.

Remark 3.3: Vol3 is the third smallest known closed orientable hyperbolic 3-manifold. Topologically Vol3 is (3,1) surgery on manifold m007 in the census of cusped hyperbolic 3-manifolds (see [W]). It is also (-3,2) (-6,1) surgery on the “left-handed Whitehead link”, link 5_2^2 in the standard knot tables. Snappea gives an experimental proof that Vol3 is hyperbolic and that its volume is that of the regular ideal 3-simplex. A rigorous proof can be found in [JR]. Previously, Hodgson-Weeks [HW1] had found an exact Dirichlet domain

for Vol3, that is, the face pairings were expressible as explicit matrices with coefficients in a finite extension F of $\mathbf{Q}$ and they obtained equations in F for the various faces. See Remark 3.14.

Remarks 3.4: i) Idea of Proof of Proposition 3.1: If N has $\maxcorona(\delta) \geq 2\pi/3$, then it must have an (L, D, R) parameter in the region $\mathcal{R} = \exp^{-1}(X_0)$, (X_0 is defined in Proposition 1.28). A geometric argument (Lemma 3.7) which utilizes Lemmas 3.5 and 3.6 shows that $R = 0$ and an algebraic argument (Lemmas 3.8, 3.9, 3.11, 3.12) shows that $L = D = \omega$, where $\exp(\omega)$ is a root of the polynomial $1 + 2d + 6d^2 + 2d^3 + d^4$. This implies ([HW1] or [JR]) that $g = \pi_1(\text{Vol3})$ and hence N is covered by Vol3. By [JR], $N = \text{Vol3}$.

ii) The proof of Proposition 3.2 will be somewhat similar to the proofs of Propositions 1.28, 2.8.

Lemma 3.5: Let $\mathcal{R} = \exp^{-1}(X_0)$ If $\alpha = (L, D, R) = (l + it, d + ib, r + ia) \in \mathcal{R} \cap \mathcal{T}$, then f_α, w_α satisfy the relations

- i) $wFwfWfwf$
- ii) $wFfwfwfwFw$

Proof: In i), ii) above and what follows below we suppress the subscripts α . Also W (resp. F) denotes w^{-1} (resp. f^{-1}). because i), ii) are cyclic permutations of the quasi-relators r_2, r_1 corresponding to the X_0 sub-box of Proposition 1.28, it follows that if $h = wFwfWfwf$ or $wFfwfwfwFw$, then $\text{Relength}(h) < \text{Relength}(f)$ throughout $\mathcal{R}$. Since $\alpha \in \mathcal{T}$, f is a shortest element and so $h = \text{id}$. ■

Lemma 3.6: The following substitutions give rise to three sets of new relators.

- a) In i), ii) replace f by w and replace w by f .
- b) In i), ii) replace f by F .
- c) In i), ii) replace w by W .

Proof: Note that replacing f by w necessitates replacing F by W , and so on.

a) First, a cyclic permutation of relator i) gives relator i) with f replaced by w and w replaced by f . Second, one readily obtains the relator $fWfwffwfwf$ from i), ii), because $fWfwf = (wFwfw)^{-1} = wfwFw = (fwfWf)^{-1}$ where the first and third equalities follow from i) and the second from ii).

b) Again it is routine to obtain b) from i), ii).

c) Conclusion c) follows from a) and b). ■

Lemma 3.7: If $(L, D, R) \in \mathcal{R} \cap \mathcal{T}$, then $R = 0$.

Proof: With respect to the parameter (L, D, R) let G be the group generated by f, w . Figure 3.1 shows a schematic picture of geodesics $B, W(B), w(B), f(w(B)), f(W(B))$. Also, it shows the images of the orthocurve O from $W(B)$ to B after translation by w, f and fw . Finally, it shows the orthocurves O_1 from $fW(B)$ to $W(B)$ and O_2 from $w(B)$ to $fw(B)$. Note that Figure 3.1 displays the situation where $\text{Re}(R) > 0$. It is also apriori possible that O_2 might intersect $w(B)$ on the positive side of $w(O)$. There are other similar possible inaccuracies.

$\sigma_1 = fwffw \in G$ sends geodesic $W(B)$ to $fw(B)$ and $\sigma_2 = wFFwF \in G$ sends the geodesic $fW(B)$ to $w(B)$. Now $\sigma_2^{-1}\sigma_1 = fWffWfwffw$ is a relator of G , since it is a

Figure 3.1

cyclic permutation of relator ii) with f replaced by w and w replaced by f . Thus $\sigma_1 = \sigma_2$ and hence $\sigma_1(O_1) = O_2$.

As in Fenchel [F] a right angled hexagon consists of a cyclically ordered 6-tuple of oriented geodesics $\lambda_1, \dots, \lambda_6$ in $\mathbf{H}^3$ such that λ_i intersects $\lambda_{i+1} \pmod{6}$ orthogonally. Each “edge” of the hexagon is labelled by the complex number e_i where one obtains λ_{i+1} from λ_{i-1} by e_i translation of $\mathbf{H}^3$ along the oriented geodesic λ_i .

(3.1) The effect of reversing the orientation of λ_i is to change e_i to $-e_i$, e_{i+1} to $e_{i+1} + \pi i$, and e_{i-1} to $e_{i-1} + \pi i$.

Figure 3.1 gives rise to the two right-angled hexagons drawn in Figure 3.2. (Figure 3.2a may be inaccurate for the following reason. It is not clear whether the head of O_1 should be placed in front of the tail of O or behind the tail of O . A similar statement holds for the tail of O_1 and for Figure 3.2b.) Assume that in Figure 3.2a, λ_1 corresponds to B and the edges are cyclically ordered counterclockwise. Then $e_6 = D, e_1 = L, e_2 = -D$. We now show that if e_5 has value c , then e_3 has value $c + \pi i$. Observe that there is an order-2 rotation τ of $\mathbf{H}^3$ about an axis orthogonal to B which reverses the orientation on B and takes the oriented orthocurve O to the oriented orthocurve $f(O)$. Since $\text{distance}(W(B), B) = \text{distance}(fW(B), B)$ it follows that $\tau(fW(B)) = -W(B)$ and $\tau(W(B)) = -fW(B)$ where the $-$ sign indicates that the orientation has been reversed. This in turn implies that $\tau(O_1) = -O_1$ and therefore using (3.1) that $e_3 = e_5 + \pi i$.

Let ϕ be the isometry of $\mathbf{H}^3$ which is an $r + i(\pi + a)$ translation of B . Thus $\phi(B) = B$, $\phi(O) = -w(O)$, $\phi(f(O)) = -fw(O)$. This implies that $\phi(W(B)) = w(B)$ and $\phi(fW(B)) = fw(B)$ which in turn implies that $\phi(O_1) = -O_2$. If the hexagon of Figure 3.2b with edges $\lambda'_1, \dots, \lambda'_6$ is counterclockwise cyclically oriented so that λ'_1 denotes

On Figure 3.3. Here O_i^* is G translation of O_i with an endpoint on B . Two such translates

on Figure 3.3. Here O_i^* is G translation of O_i with an endpoint on B . Two such translates appear in Figure 3.3, one where O_i^* points in Figure 3.3 and one where O_i^* points out. Call the former (resp. latter) the pointing in (resp. out) O_i^* . Actually Figure 3.3 includes 3 more relations. Because the oriented O_1 is a G -translate of the oriented O_2 and f is a primitive element of G which fixes B , it follows that

$$\text{distance}((\text{pointing in } O_1^*), (\text{pointing in } O_2^*)) = 0 \pmod{L}$$

and

$$\text{distance}(\text{(pointing out } O_1^*), \text{(pointing out } O_2^*)) = 0 \pmod{L}.$$

Finally $\text{distance}(w(O), O) = R$.

We therefore obtain the following two equations

$$(3.2) \quad c - R + L + c + \pi i = 0 \pmod{L} \quad c - L + R + c + \pi i = 0 \pmod{L}$$

and hence

$$(3.3) \quad 2R = 0 \pmod{L} \quad 4c = 0 \pmod{L}.$$

Using the L' and R' ranges for X_0 provided in Proposition 1.28, it is easy to compute that for each element of $\mathcal{R} = \exp^{-1}(X_0)$, $|\operatorname{Re}(R)| < |\operatorname{Re}(L)/2|$. It then follows that $R = 0$ for $(L, D, R) \in \mathcal{R} \cap \mathcal{T}$. ■

Lemma 3.8: If $(L, D, R) \in \mathcal{R} \cap \mathcal{T}$, then $L = D$.

Proof: We will now use the exponential coordinates $l = \exp(L)$, $d = \exp(D)$. These l, d should not be confused with the $l + it, d + ib$ used above. In the following calculations Mathematica [Math] was used to perform matrix multiplication of 2×2 matrices with coefficients rational functions in the variables $\sqrt{l}$, $\sqrt{d}$. We will follow Mathematica's notation (for example, in Mathematica's notation the 2×2 matrix (a_{ij}) is $\{\{a_{11}, a_{12}\}, \{a_{21}, a_{22}\}\}$). In particular, plugging in $R = 0$ in Lemma 1.24 we get the following matrix representations of f, F, w, W . Because the R term drops out, we can express the matrices of w and W as functions of d alone.

$$f[l_-] = \{\{\operatorname{Sqrt}[l], 0\}, \{0, 1/\operatorname{Sqrt}[l]\}\}$$

$$F[l_-] = \{\{1/\operatorname{Sqrt}[l], 0\}, \{0, \operatorname{Sqrt}[l]\}\}$$

$$w[d_-] = \{\{1/2(\operatorname{Sqrt}[d] + 1/\operatorname{Sqrt}[d]), 1/2(\operatorname{Sqrt}[d] - 1/\operatorname{Sqrt}[d])\}, \\ \{1/2(\operatorname{Sqrt}[d] - 1/\operatorname{Sqrt}[d]), 1/2(\operatorname{Sqrt}[d] + 1/\operatorname{Sqrt}[d])\}\}$$

$$W[d_-] = \{\{1/2(\operatorname{Sqrt}[d] + 1/\operatorname{Sqrt}[d]), 1/2(-\operatorname{Sqrt}[d] + 1/\operatorname{Sqrt}[d])\}, \\ \{1/2(-\operatorname{Sqrt}[d] + 1/\operatorname{Sqrt}[d]), 1/2(\operatorname{Sqrt}[d] + 1/\operatorname{Sqrt}[d])\}\}$$

Let Y be the relator $F.w.f.w.f.W.f.w.f.w$, which is a cyclic permutation of relator i) of Lemma 3.4. Multiplying this product of 10 matrices we obtain the following matrix for Y which we know is I .

$$Y[l_-, d_-] = \{\{((1 + d) * (1 - 2 * d^2 + d^4 + 8 * d * l - 16 * d^2 * l \\ + 8 * d^3 * l - 2 * l^2 + 4 * d * l^2 - 4 * d^2 * l^2 + 4 * d^3 * l^2 - \\ 2 * d^4 * l^2 + l^4 + 4 * d * l^4 + 6 * d^2 * l^4 + 4 * d^3 * l^4 \\ + d^4 * l^4)) / (32 * d^{(5/2)} * l^{(3/2)}),$$

$$((-1 + d) * (1 + 4 * d + 6 * d^2 + 4 * d^3 + d^4 + 4 * d * l + \\ 8 * d^2 * l + 4 * d^3 * l - 2 * l^2 - 12 * d^2 * l^2 - 2 * d^4 * l^2 + \\ 4 * d * l^3 + 8 * d^2 * l^3 + 4 * d^3 * l^3 + l^4 + 4 * d * l^4 + \\ 6 * d^2 * l^4 + 4 * d^3 * l^4 + d^4 * l^4)) / (32 * d^{(5/2)} * l^{(3/2)})\},$$

$$\begin{aligned} & \{((-1 + d) * (1 + 4 * d + 6 * d^2 + 4 * d^3 + d^4 + 4 * d * l + \\ & 8 * d^2 * l + 4 * d^3 * l - 2 * l^2 - 12 * d^2 * l^2 - 2 * d^4 * l^2 + \\ & 4 * d * l^3 + 8 * d^2 * l^3 + 4 * d^3 * l^3 + l^4 + 4 * d * l^4 + \\ & 6 * d^2 * l^4 + 4 * d^3 * l^4 + d^4 * l^4)) / (32 * d^{(5/2)} * l^{(3/2)}), \end{aligned}$$

$$\begin{aligned} & ((1 + d) * (1 + 4 * d + 6 * d^2 + 4 * d^3 + d^4 - 2 * l^2 + 4 * d * l^2 - \\ & 4 * d^2 * l^2 + 4 * d^3 * l^2 - 2 * d^4 * l^2 + 8 * d * l^3 - \\ & 16 * d^2 * l^3 + 8 * d^3 * l^3 + l^4 - 2 * d^2 * l^4 + d^4 * l^4)) \\ & / (32 * d^{(5/2)} * l^{(3/2)}) \} \} \end{aligned}$$

Since G is generated by f , an L translation along B , and w , a D translation along C , it follows from Lemma 3.6 that the relation $Y = I$ holds with l and d switched. Thus $0 = Y_{12}$, and $0 = Y_{12}$ (with l, d switched) which implies that

$$\begin{aligned} 0 = & (1 + 4 * d + 6 * d^2 + 4 * d^3 + d^4 + 4 * d * l + 8 * d^2 * l + \\ & 4 * d^3 * l - 2 * l^2 - 12 * d^2 * l^2 - 2 * d^4 * l^2 + \\ & 4 * d * l^3 + 8 * d^2 * l^3 + 4 * d^3 * l^3 + l^4 + 4 * d * l^4 + \\ & 6 * d^2 * l^4 + 4 * d^3 * l^4 + d^4 * l^4) - \\ & (1 + 4 * l + 6 * l^2 + 4 * l^3 + l^4 + 4 * l * d + 8 * l^2 * d + \\ & 4 * l^3 * d - 2 * d^2 - 12 * l^2 * d^2 - 2 * l^4 * d^2 + \\ & 4 * l * d^3 + 8 * l^2 * d^3 + 4 * l^3 * d^3 + d^4 + 4 * l * d^4 + \\ & 6 * l^2 * d^4 + 4 * l^3 * d^4 + l^4 * d^4) = \end{aligned}$$

$$4 * (1 + d)^2 * (1 + l)^2 * (-d + l) * (-1 + d * l).$$

This implies that $d = l$ and hence $D = L$ or we obtain one of the following solutions which contradicts the condition $\text{Re}(D) > 0$. The solution $d = -1$ implies $D = \ln(d) = \ln(-1) = \pi i$. The solution $d = 1$ implies $D = 0$. The solution $d * l = 1$ implies that $d = 1/l$ and hence $D = \ln(d) = \ln(1/l) = -\ln(l) = -L$ and hence $\text{Re}(D) < 0$. ■

Lemma 3.9: If $(L, D, R) \in \mathcal{R} \cap \mathcal{T}$, then $d = \exp(D)$ is a root of the polynomial

$$1 + 2 * d + 6 * d^2 + 2 * d^3 + d^4.$$

Proof: The equation $Y_{12} = 0$ yields

$$\begin{aligned}
 0 = & 1 + 4 * d + 6 * d^2 + 4 * d^3 + d^4 + 4 * d * l + 8 * d^2 * l + 4 * d^3 * l - 2 * l^2 - \\
 & 12 * d^2 * l^2 - 2 * d^4 * l^2 + 4 * d * l^3 + 8 * d^2 * l^3 + 4 * d^3 * l^3 + l^4 + 4 * d * l^4 + \\
 & 6 * d^2 * l^4 + 4 * d^3 * l^4 + d^4 * l^4.
 \end{aligned}$$

Setting $l = d$ we obtain

$$\begin{aligned}
 0 = & 1 + 4 * d + 8 * d^2 + 12 * d^3 - 2 * d^4 + 12 * d^5 + 8 * d^6 + 4 * d^7 + d^8 = \\
 & (1 + 2 * d - 2 * d^2 + 2 * d^3 + d^4) * (1 + 2 * d + 6 * d^2 + 2 * d^3 + d^4).
 \end{aligned}$$

On the other hand setting $l = d$ in the equation $Y_{11} = 1$ we obtain

$$32d^5 = (1 + d)(1 + 4 * d^2 - 12 * d^3 + 6 * d^4 + 8 * d^5 + 4 * d^6 + 4 * d^7 + d^8)]$$

and so

$$0 = (-1 + d) * (1 + 2 * d + 6 * d^2 + 2 * d^3 + d^4) * (-1 + 4 * d^3 + d^4)$$

The only common solutions to these equations are the roots of the equation

$$(3.4) \quad (1 + 2 * d + 6 * d^2 + 2 * d^3 + d^4) \quad \blacksquare$$

Remark 3.10: The two facts $Y = I$, and l, d can be switched in Y follow from relator i) of Lemma 3.4 and $R = 0$. Relator ii) was used in the proof that $R = 0$.

Lemma 3.11: The roots of $1 + 2 * d + 6 * d^2 + 2 * d^3 + d^4$ are

$$\begin{aligned}
 & (-1 + i * \sqrt{3})/2 - (-6 - 2 * i * \sqrt{3})^{(1/2)}/2 \\
 & (-1 + i * \sqrt{3})/2 + (-6 - 2 * i * \sqrt{3})^{(1/2)}/2 \\
 & (-1 - i * \sqrt{3})/2 - (-6 + 2 * i * \sqrt{3})^{(1/2)}/2 \\
 & (-1 - i * \sqrt{3})/2 + (-6 + 2 * i * \sqrt{3})^{(1/2)}/2
 \end{aligned}$$

■

Remark 3.12: Note that if x is a root of $1 + 2 * d + 6 * d^2 + 2 * d^3 + d^4$, then so are $\bar{x}$, $1/x$ and $1/\bar{x}$.

Lemma 3.13: If $(L, D, R) \in \mathcal{R} \cap \mathcal{T}$, then

$$\begin{aligned}
 D = L = & \ln((-1 + i * \sqrt{3})/2 - (-6 - 2 * i * \sqrt{3})^{(1/2)}/2) \\
 = & \omega \approx 0.83144294552931 - 1.945530759503636 * i.
 \end{aligned}$$

Proof: The other 3 solutions are $-L$, $Re(L) - Im(L)$, $-Re(L) + Im(L)$ and lie outside $\mathcal{R}$. The above solution lies in $\mathcal{R}$. ■

Remark 3.14: In our language, Hodgson and Weeks [HW1] knew that $\pi_1(\text{Vol3})$ was generated by f, w with $D = L = \omega$ and $R = 0$. Also that the various solutions of (3.4) corresponded to symmetries of Vol3.

Corollary 3.15: Vol3 is the unique hyperbolic 3-manifold with ζ associated parameter values in $\mathcal{S} \cap X_0$.

Proof of Proposition 3.1: By Proposition 2.8 if $\maxcorona(\delta) \geq \ln(3)/2$, then the parameter for a 2-generator subgroup G of $\pi_1(N)$ lies in $\mathcal{S} \cap X_0$. Since $G = \pi_1(\text{Vol3})$, N is covered by Vol3. By Reid (see [JR]) Vol3 only covers Vol3. Therefore $N = \text{Vol3}$. ■

Proof Proposition 3.2: We show that the Dirichlet insulator associated to a shortest geodesic δ in N satisfies the insulator condition if $\mathcal{C}(O(2)) < 113.16$ degrees. Here $O(2) = \text{distance}(B, \text{second closest lift of } \delta)$ and $O(1) = \omega$ corresponds to the closest lift. This actually requires that we be a bit more precise, so we insert the following definition.

Definition 3.16: Let δ be a geodesic in the hyperbolic 3-manifold N and $\{\delta_i\}_{i \geq 0}$ be the preimages of δ in $\mathbf{H}^3$. Define an equivalence relation on $\{\delta_i\}_{i \geq 1}$ by saying that $\delta_i = \delta_j$ if either

i) there exists a $g \in \pi_1(N)$ such that $g(\delta_0) = \delta_0$ and $g(\delta_i) = \delta_j$

or

ii) there exists $g \in \pi_1(N)$ such that $g(\delta_i) = \delta_0$ and $g(\delta_0) = \delta_j$.

Call an equivalence class an *ortho-equivalence class*. Consider the collection $\mathcal{O}$ of complex numbers $\{\text{distance}(\delta_0, \delta_i) \mid i > 0 \text{ and only one } \delta_i \text{ is represented in each equivalence class}\}$ Now order $\mathcal{O}$ to obtain the *ortholength spectrum* of δ , $\{O(1), O(2), \dots\}$ where $i \leq j$ implies $\text{Re}(O(i)) \leq \text{Re}(O(j))$.

The *based ortholength spectrum* consists of all distinct pairs of complex numbers of the form $\{(\text{distance}(C, \text{ortholine from } B \text{ to } g(B)), \text{distance}(B, g(B))) \mid g \in \pi_1(N)\}$.

The geodesic plane midway between B and $w^{-1}(B)$ intersects the $B - C$ plane in a geodesic E at distance $\text{Re}(\omega)/2 = \text{Re}(\text{length } f)/2$ from B . Conjugate $\pi_1(N)$ so that f is still an ω translation of B and so that one endpoint of E is at $(1, 0)$ and the other endpoint is at $(x, 0)$, where $x > 1$. By [Beardon; p. 166] $x < 23.815$. Thus the Dirichlet insulator λ (resp. $w(\lambda)$) between $B, w^{-1}(B)$ (resp. $B, w(B)$) is symmetric about the x -axis and lies within the circle passing through $(1, 0), (23.815, 0)$ (resp. $(-1, 0), (-23.815, 0)$). By [G; Lemma 4.7] this circle takes up a visual angle of less than 133.68 degrees. Now f is the composition of an $\exp(\text{Re}(\omega))$ homothety centered about the origin and an $\text{Im}(\omega)$ radian ≈ -111.4707 degree rotation. Because $\exp(4 * \text{Re}(\omega)) > 27.82 > 23.815$ it follows that the geodesic E is taken “beyond” E by w^4 . In fact, we see that $\lambda \cap (f^n(\lambda) \cup f^n w(\lambda)) = \emptyset$ if $|n| \geq 4$. Therefore if there was a tri-linking among three insulators associated to the orthoclass of $w(B)$, there would be a tri-linking involving 3 circles from the collection $\{f^n w(\lambda), f^n(\lambda) \mid -3 \leq n \leq 0\}$.

Since $\mathbf{S}_\infty^2$ is rotated by at most 111.48 degrees under $f^{\pm 1}$, and λ takes up less than 133.68 degrees B -visual angle it follows that $f^{-1}(\lambda) \cup \lambda$ take up less than $133.68 + 111.48 = 245.06$ degrees B -visual angle. Similar arguments show that if λ and one of $f^n(\lambda)$ or $f^m w(\lambda)$ nontrivially intersect, then the union cannot take up more B -visual angle, in fact except for $f^\pm(\lambda)$, it takes up less. See Figure 3.4 which shows the union of $\{f^n w(\lambda), f^n(\lambda) \mid$

$-3 \leq n \leq 0\}$. Therefore, if the union of three such circles was connected, they would take up at most $133.68 + 2(111.48) = 356.64$ degrees of B -visual angle and hence would not create a trilinking.

Now suppose that $C(O(2)) < 113.16$. Thus any insulator associated to a translate of B not in the $O(1)$ class would take less than 113.16 degrees visual angle. There are three cases to consider: trilinking involving no $O(1)$ insulators; trilinking involving exactly one $O(1)$ insulator; trilinking involving exactly two $O(1)$ insulators. The case of no $O(1)$ insulators cannot occur because $3(113.16) < 360$. The case of exactly one $O(1)$ insulator cannot occur because $B\text{-visual angle}(O(1)) + 2(C(O(2))) < 133.68 + 2(113.16) = 360$. Finally, the case of exactly two $O(1)$ insulators cannot occur, because the two $O(1)$ insulators would take up at most 245.06 degrees of visual angle (see the above paragraph) and adding to this the fact that $C(O(2)) < 113.16$ produces less than 360 degrees.

The proof of Proposition 3.2 is now completed by the following

Lemma 3.17: If δ is a shortest geodesic in Vol 3, then $C(O(2)) < 113.16$.

Proof: Step 1: $\text{Re}(O(2)) > \text{Re}(O(1))$

Proof of Step 1. If $\text{Re}(O(2)) = \text{Re}(O(1))$, then it follows by Proposition 3.1 that $O(2) = O(1) = \omega$. Furthermore the collection of orthocurves must appear symmetrically on the geodesic B , i.e. if $\text{distance}(O(2)\text{-ortholine}, C) = x + yi$, with $0 \leq x$, x minimal, then there is an ortholine at distance $n(x + yi)$ with $n \in \mathbf{Z}$ along B from C whose corresponding ortholength is ω . Use the fact that if $v \in \pi_1(\text{Vol}3)$ is the element with $\text{distance}(v(B), B) = O(2)$ as above, then the group generated by v, f is conjugate to the group generated by w, f .

If $x = 0$, and $y > 0$ is minimal, then $y = \pi/m$. Using Fenchel's law of cosines [F; p. 83], it follows that if $m = 2$, then there exists an $\bar{\omega}$ ortholength thereby contradicting Proposition 3.1. See Figure 3.5. If $m > 2$, then a similar argument shows that there exists a real ortholength less than $\text{Re}(\omega)$.

If $x > 0$ choose m minimal so that $mx = \text{Re}(\omega)$. By replacing y by $y + \pi i$, if necessary, we can assume that $m(x + yi) = \omega$. Therefore an $x + iy$ translation τ along B descends to a $\mathbf{Z}/m$ action ϕ on Vol3. Any lift of ϕ^n is a conjugate of τ^n which is fixed-point free or the identity. This contradicts the fact that Vol3 only covers Vol3. ■

$$\text{Cosh}(P) = \text{Cosh}^2(\omega) + \text{Sinh}^2(\omega) \text{Cosh}(\pi i)$$

Step 2: $C(O(2)) < 113.16$

Figure 3.5

Proof of Step 2. We obtain this result with computer assistance in a manner similar to the proofs of Propositions 1.28 and 2.8. Our parameter space $\mathcal{W}$ is the usual initial box. As before, a parameter gives rise to a group G with generators f, v . (Here we reserve the letter w to denote one of the generators of $\pi_1(\text{Vol3})$.) We consider the parameters $U \subset \mathcal{W}$ such that f, v generate a group G where f is of minimal length, and $\text{maxcorona}(\delta_f) = C(v) \geq 113.16$. If Step 2 was false then $U \neq \emptyset$ for it contains the 2-generator subgroup of $\pi_1(\text{Vol3})$ generated by f, v where $\text{distance}(v(B), B) = O(2)$. We now show that $U = \emptyset$ as follows.

We partition $\mathcal{W}$ into regions $\mathcal{W}_i$ such that each $\mathcal{W}_i$ can be eliminated for one of the following reasons.

z) $\mathcal{W}_i = X_0$.

a) There exists no $\beta \in \mathcal{W}_i$ such that $\text{length}(f_\beta) \in \mathcal{L}(X_0)$. In particular, $\text{length}(f_\beta) \neq \omega$ throughout $\mathcal{W}_i$.

b) $\mathcal{W}_i$ has some L values in $\mathcal{L}(X_0)$ but there exists no $\beta \in \mathcal{W}_i$ such that the real part of $\text{distance}(v_\beta(B), B)$ is greater than the minimum d value for X_0 . In particular, $\text{Re}(\text{distance}(v_\beta(B), B)) \leq \text{Re}(\omega)$ throughout $\mathcal{W}_i$.

c) There exists a killerword h in f, w, f^{-1}, w^{-1} , such that $h_\beta \neq \text{id}$ and $\text{Relength}(h_\beta) < \text{Relength}(f_\beta)$ for all $\beta \in \mathcal{W}_i$.

It turns out that a Corona condition is not needed—c) is sufficient to generate all the killer words we need!

There are files containing the partition of $\mathcal{W}$ and the associated conditions/killerwords, and *fudging* verifies that they indeed work. *Fudging* actually takes care of the sub-boxes $X_0, \dots, X_6$ all at once, and the associated files reflect that fact.

As noted earlier, *fudging* works with the exponentiated versions of the above conditions. ■

Here is an experimental “proof” of Lemma 3.17. In [HW2] an algorithm is given to compute, with multiplicities, the length spectrum of a hyperbolic 3-manifold M , given a Dirichlet domain for M . Weeks has observed [Weeks, personal communication] that a very

similar argument gives an algorithm to compute the based ortholength spectrum. In fact an analogue to Proposition 1.6.2 [HW2], (with an analogous proof) is the following

Lemma 3.18 (Weeks): Let M be a closed orientable 3-manifold having a Dirichlet domain $\mathcal{D}$ with basepoint x and with spine radius r . Let δ be a geodesic of length $l + it$. To compute all the based ortholengths of real length less than or equal to λ with basing less than or equal to $l/2$ from some point on δ_0 (a preimage of δ) it suffices to find all translates $g\mathcal{D}$ satisfying $\rho(x, gx) \leq 2r + 2\text{Arccosh}(\cosh(l/2) \cosh(\lambda/2))$.

Proof: As in [HW2] we can assume that $\rho(\delta_0, x) \leq r$. The 0-basing on δ_0 will be given by the oriented perpendicular P from δ_0 to x . Figure 3.6 shows that if there is a translate $\delta_i = g(\delta_0)$ based at distance $\leq l/2$, at real distance $\leq \lambda$ from δ_0 , then $\rho(g(x), x) \leq \lambda + l + 2r$. As in [HW2] an application of the hyperbolic cosine law yields the better estimate of the Lemma. ■

Figure 3.6

Provided one is given a Dirichlet domain, [HW2] gives an efficient algorithm to find these g 's. Finally to each such g one computes the basing and distance from $g(\delta_0)$ to δ_0 .

The collection of ortholengths with basings $\leq l/2$ contains at least 2 representatives for each ortholength class, thus the Weeks algorithm can be used to give lower bounds on the various $O(i)$'s. Snappea computes a Dirichlet domain for Vol3 with spine radius ≤ 0.68 . Because $l < 0.83145$, taking $\lambda = 1.24$ we obtain $2r + 2\text{arccosh}(\cosh(l/2) \cosh(\lambda/2)) < 2.89$. This algorithm has been implemented on an undistributed version of Snappea, and provided the following estimates. Note that $\text{Re}(O(2)) \geq 1.24$ is sufficient to guarantee that $\mathcal{C}(O(2)) < 113.16$ degrees.

$$O(1) \approx .83144 - 1.94553I,$$

$$O(2) \approx 1.3170 - \pi I,$$

$$O(3) = O(4) \approx 1.4197 + 1.0963I,$$

$$O(5) \approx 1.9769 - 1.2995I.$$

These estimates were found using a “tiling” of radius $3.00 > 2.89$, which is sufficient for “proving” that for Vol3, $\text{Re}(O(2)) > 1.24$. ■

Remark 3.19: This experimental proof should be easily rigorizable by implementing Weeks’s algorithm using exact arithmetic.

Chapter 4: Applications

We provide some applications. First, we give a partial answer to Question 1.16. Second a lower bound for the volume of hyperbolic 3-manifolds is produced. Finally, we give a relationship between isotopic closed curves in a hyperbolic 3-manifold and essential links in B^3 .

Theorem 4.1: If δ is a shortest geodesic in a closed orientable hyperbolic 3-manifold N , then either $\text{tuberadius}(\delta) \geq 1.059191579962\dots/2$ or $N = \text{Vol3}$.

Proof: If $\text{tuberadius}(\delta) = d/2 < \ln(3)/2$, then by Corollary 1.29 ii, $d \in$

$$\begin{aligned} & [0.831426508686\dots, 0.831461989726\dots] \cup [1.068029907104\dots, 1.068134862048\dots] \cup \\ & [1.072078514724\dots, 1.072622271888\dots] \cup [1.094788113123\dots, 1.095007375882\dots] \cup \\ & [1.094973832380\dots, 1.095231885426\dots] \cup [1.059191579962\dots, 1.060372139694\dots]. \end{aligned}$$

If $d < 1.059191579962\dots$, then by Proposition 1.28 the parameter $(L, D, R) \in \mathcal{P}'$ associated to N must be in $\mathcal{R} \cap \mathcal{T} = \exp^{-1}(X_0 \cap \mathcal{S})$. It then follows by Corollary 3.15 that $N = \text{Vol3}$. ■

Conjecture 4.2: If δ is a shortest geodesic in a closed orientable hyperbolic 3-manifold N , then either $\text{tuberadius}(\delta) > \ln(3)/2$ or N is one of six exceptional manifolds.

Remark 4.3: Vol3 is one of these manifolds. As in Remark 1.32, three others are conjecturally, $s479(-3, 1)$, $s778(-3, 1)$, $v2678(2, 1)$. These correspond to sub-boxes X_5, X_2, X_1 respectively.

The conjectured fundamental groups of the six manifolds are $\langle f, w; r_1(X_k), r_2(X_k) \rangle$ for $k \in 0, \dots, 6$. (The groups for $k = 5, 6$ are isomorphic). Using [Be] one can get explicit Heegaard genus 2 descriptions of all the conjectured manifolds.

One could prove Conjecture 4.2 by first showing that for each k , $\mathcal{T} \cap X_k$ is a point T_k . Let M_k be the hyperbolic 3-manifold which corresponds to T_k . Second show that M_k nontrivially covers no 3-manifold. This procedure was carried out in Chapter 3 for the subbox X_0 .

Remarks 4.4: The previous best lower bound for the volume of hyperbolic 3-manifolds was on the order of 0.001 (see [GM1] and [M2]). Using the results of this paper and the method of [M1] it is easy to improve this to 0.1. However, Gehring and Martin provide an improved tube-volume formula in [GM2] and we use their formula to get a lower bound of 0.16668.... The Gehring-Martin tube-volume formula for manifolds (as opposed to orbifolds) is

$$\mathcal{V}(t) = \sqrt{3} \tanh(t) \cosh(2t) \text{Arcsinh}^2(\sinh(t)/\cosh(2t))$$

where t is the radius of the embedded solid tube. Note that the length of the core geodesic is irrelevant.

Theorem 4.5: $\frac{5}{2\sqrt{3}} \text{Arcsinh}^2(\frac{\sqrt{3}}{5}) = 0.16668\dots$ is a lower bound for the volume of closed hyperbolic 3-manifolds.

Proof: [GM2; Corollary 1.7] applies the tube-volume formula $\mathcal{V}(t)$ to tubes of radius at least $\ln(3)/2$ and produces

$$\text{Vol}(N) \geq \mathcal{V}(\ln(3)/2) = \frac{5}{2\sqrt{3}} \text{Arcsinh}^2\left(\frac{\sqrt{3}}{5}\right) = 0.16668\dots$$

Corollaries 1.29 and 3.15 imply that if the tube radius of a shortest geodesic in N is less than $\ln(3)/2$, then either $N = \text{Vol}3$ or N contains an embedded open tube of radius $d/2$, where $d \in \text{Re}(\ln(\mathcal{D}(X_k)))$, about a geodesic of length $l \in \text{Re}(\ln(\mathcal{L}(X_k)))$ for some $k \in 1, \dots, 6$. As in the Theorem 4.1 we compute that $l \geq 1.059536368901\dots$

In the first case, $\text{Vol}(N) = \text{Vol}(\text{Vol}3) = 1.01\dots$, while in the second case l and d are bounded as follows: $l \geq 1.059536368901\dots$ and $d \geq 1.059191579962\dots$. Plugging these into the tube-volume formula $\pi l \sinh^2(d/2)$ we get $\text{Vol}(N) \geq 1.02419\dots$ ■

Theorem 4.6: Let k_1, k_2 be simple closed curves in N such that k_1 is a geodesic. Then k_1 is isotopic to k_2 if and only if as B^3 -links $q^{-1}(k_1)$ is equivalent to $q^{-1}(k_2)$ where $q : \mathbf{H}^3 \rightarrow N$ is the universal covering projection.

Proof: Apply Corollary 5.6 of [G]. Recall that an equivalence between B^3 -links Γ, Δ is a homeomorphism of B^3 which takes Γ to Δ and fixes S^2 pointwise. ■

Remark 4.7: A similar argument extends Theorem 4.6 to homotopy essential links which lift to trivial B^3 -links. The general case of Conjecture 5.5A of [G] is still open.

Chapter 5: Conditions and Sub-Boxes

As described in Section 1, our goal is to kill off all points in $S \subset \mathbf{C}^3$, but for computational reasons we will actually work with the box $B \supset S$. We will decompose B into a collection of sub-boxes such that each sub-box has an associated “condition” that will describe how to kill off that entire sub-box. The set-up for describing these sub-boxes will be given in Section 3.

We now list the conditions used to kill off the sub-boxes. There are two types of conditions: the trivial and the interesting. The trivial conditions kill off sub-boxes in W by noting that the sub-box in question misses S . The interesting conditions are where the real work is done, and they require a killer word in f, w, f^{-1}, w^{-1} to work their magic.

To be consistent with the computer program *verify* we use the following notation. $L' = z_0 + iz_3$, $D' = z_1 + iz_4$, and $R' = z_2 + iz_5$. Here $(L', D', R') \in W$ and $L' = \exp(L) = \exp(l + it)$, $D' = \exp(D) = \exp(d + ib)$, $R' = \exp(R) = \exp(r + ia)$.

The Trivial Conditions 5.1:

Condition ‘s’ (short): Tests that all points in the sub-box have $|z_0 + iz_3| < 1.10274$. This ensures that $\exp(l) = |\exp(L)| = |L'| = |z_0 + iz_3| < 1.10274 < \exp(0.0978)$, and Definition 1.14 tells us that we are outside of $S = \exp(T)$

Condition ‘l’ (long): Tests that all points in the sub-box have $|z_0 + iz_3| > 3.63201$. This ensures that $\exp(l) = |\exp(L)| = |L'| = |z_0 + iz_3| > 3.63201 > \exp(1.2897845)$ and

we are outside of S . Here we have improved S to allow for the value computed in the proof of Proposition 1.13, rather than the cruder value 1.29.

Condition ‘n’ (near): Tests that all points in the sub-box have $|z_1 + iz_4| < 1$. This ensures that $\exp(d) = |\exp(D)| = |D'| = |z_1 + iz_4| < 1 = \exp(0)$ and we are outside of S . Actually, we used a stronger condition in Definition 1.14 ($l/2 \leq d$).

Condition ‘f’ (far): Tests that all points in the sub-box have $|z_1 + iz_4| > 3$. This ensures that $\exp(d) = |\exp(D)| = |D'| = |z_1 + iz_4| > 3 = \exp(\ln 3)$ and we are outside of S .

Condition ‘w’ (whirle big): Tests that all points in the sub-box have $\frac{|z_2 + iz_5|^2}{|z_0 + iz_3|} > \sqrt{\exp(l)} = \exp(l/2)$ and we are outside of S . In the computer program, this test requires a round-off error analysis. As such, the formula in the program is more complicated than expected. See Chapters 7 and 8 for a discussion of round-off error.

Condition ‘W’ (whirle small): Tests that all points in the sub-box have $|z_2 + iz_5| < 1$. This ensures that $\exp(r) = |\exp(R)| = |R'| = |z_2 + iz_5| < 1 = \exp(0)$ and we are outside of S .

The Interesting Conditions 5.2:

Condition ‘L’: This condition comes equipped with a killer word k in f and w , and tests that all points in the sub-box have $|\exp(\text{length}(k))| < |L'| = |\exp(L)|$, where $\text{length}(k)$ means the length of the isometry determined by k . This, of course, contradicts the fact that L is the length of the shortest geodesic.

It is easy to carry out the test $|\exp(\text{length}(k))| < |L'|$ because Lemma 1.25a) can be used. Note that in *verify* the function which computes $\exp(\text{length})$ is called *length*.

Of course, Condition ‘L’ also checks that the isometry corresponding to the word k is not the identity.

Condition ‘O’: This condition comes equipped with a killerword k in f and w , and tests that all points in the sub-box have $|\exp(\text{distance}(k(B), B))| < |D'| = |\exp(D)|$. This, of course, contradicts the “nearest” condition.

It is easy to carry out the test $|\exp(\text{distance}(k(B), B))| < |D'|$ because Lemma 1.25b) can be used. Note that in *verify* the function which computes $\exp(\text{distance}(k(B), B))$ is called *orthodist*.

Also, Condition ‘O’ checks that the isometry corresponding to the word k does not take the axis of f to itself. bigskip **Condition ‘2’:** This is just the ‘L’ condition without the “not-the-identity” check, but with the additional proviso that k is of the form $f^p w^q$. This ensures that k is not the identity, because for k to be the identity f and w would have to have the same axis, which contradicts the fact that d can be taken to be greater than or equal to $l/4$.

Condition ‘conjugate’: There is one other condition that is used to eliminate points in W . Following Definition 1.14 (and Lemma 1.15) we eliminate all boxes with $0 < t \leq \pi$.

Of course, after exponentiating $L = l + it$, this corresponds to eliminating all boxes with $z_3 > 0$. Specifically, we toss all sub-boxes of W whose fourth entry is a 1. This condition does not appear in *verify* and *fudging* because it is applied “outside” of these programs, as described at the end of this Chapter.

Construction 5.3: We now give the method for describing the roughly 930 million sub-boxes that the initial box W is sub-divided into.

All sub-boxes are gotten by sub-division of a previous sub-box along a real hyper-plane mid-way between parallel faces of the sub-box before sub-division. Of course, these midway planes are of the form $x_i = \text{a constant}$. We use 0’s and 1’s to describe which half of a sub-divided sub-box to take (0 corresponds to lesser x_i values). For example, 0 describes the box $W \cap \{(x_0, x_1, x_2, x_3, x_4, x_5) : x_0 \leq 0\}$, 010 describes the box $W \cap \{(x_0, x_1, x_2, x_3, x_4, x_5) : x_0 \leq 0, x_1 \geq 0, x_2 \leq 0\}$, and so on.

In this way, we get a 1-to-1 correspondence between strings and sub-boxes. If s is a string of 0’s and 1’s, then let $Z(s)$ denote the box corresponding to s . The range of values for the i -th coordinate in the sub-box $Z(s)$ is related to the binary fraction $0.s_i s_{i+6} \dots s_{i+6k}$. The two sub-boxes gotten from subdividing $Z(s)$ are $Z(s0)$ and $Z(s1)$.

The directions of sub-division cycle among the various coordinate axes: the n -th sub-division is across the $(n \bmod 6)$ -th axis. The dimensions of the top-level box W were chosen so that sub-division is always done across the longest dimension of the box, and so that all of the sub-boxes are similar. This explains the factor of $2^{(5-i)/6}$ in Definition 1.22.

To kill a sub-box $Z(s)$, the checker program has two (recursive) options: use a condition (and, if necessary, an associated killer word) to kill $Z(s)$ directly, or first kill $Z(s0)$ and then kill $Z(s1)$.

There is also a third option: don’t kill $Z(s)$, and instead mark s as omitted. Any omitted sub-boxes are checked with another instance of the checker program, unless the sub-box is one of the 7 exceptional sub-boxes (11 before joining abutters).

Thus, a typical output from *verify* would be

verified000000111101111111 – {0000001111011111110000000111101111111110}

Which means that the sub-box $Z(000000111101111111)$ was killed except for its sub-boxes $Z(0000001111011111110)$ and $Z(00000011110111111110)$. The output

verified0000001111011111110 – { }.

and

verified00000011110111111110 – { }.

shows that these boxes were subsequently killed as well, and thus the entire sub-box $Z(000000111101111111)$ has been killed.

Instead of immediately working on killing the top-level box, we subdivide in the six co-ordinate directions to get the 64 sub-boxes

$Z(000000), Z(000001), Z(000010), Z(000011), \dots, Z(111111)$.

We then throw out the ones with fourth co-ordinate equal to 1 (thanks to Definition 1.14 and Lemma 1.15), leaving us with the 32 sub-boxes

$$Z(000000), Z(000001), Z(000010), Z(000011), \dots, Z(111011).$$

We then use *verify* to kill these, with the exception of the 7 exceptional boxes (11 before joining abutters together) listed in Proposition 1.28.

The choices in *verify* are made for it by a sequence of integers given as input. The sequence of integers containing the directions for killing $Z(000000)$ is contained in the file data6/000000. In such a sequence, 0 tells *verify* to sub-divide the present box (by $x_i = c$), to position itself on the "left-hand" box ($x_i \leq c$) created by that sub-division, and to read in the next integer in the sequence. A positive integer n tells *verify* to kill the sub-box it is positioned at directly, using the condition (and killer word, if necessary) on line n in the 'conditionlist' file, and to then position itself at the "next" natural sub-box. -1 tells *verify* to omit the sub-box, and mark it as skipped (the sequence of integers used in killing the skipped box $Z(s)$ is contained in a file data6/s)..

The checker program *verify*, its inputs, and the list of conditions will be available from the Geometry Center. Details about how to get them can be found at

<http://www.geom.umn.edu:/locate/HomotopyHyperbolic>

Similarly for the program *fudging* which is used on the 7 exceptional boxes.

Example 5.4: To illustrate the checking in action, this is a (non-representative) example, which shows how the sub-box $Z(s)$ (minus a hole) is killed, where

$$s = 00100011000111011100111100010111111101111100111001111000001111011110111.$$

The input associated with this sub-box is

$$(0, 0, 0, 1929, 12304, 0, 0, 7, 0, 1965, 0, 1929, 1929, 1996, -1),$$

which causes the program to kill $Z(s)$ in the following fashion:

```
kill Z(s):
  kill Z(s0):
    kill Z(s00):
      kill Z(s000) with condition 1929 = "L(FwFWFWfFWFWfWfwfw)"
      kill Z(s001) with condition 12304 = "L(FwfWFFFWfWfwfWfwfw)"
    kill Z(s01):
      kill Z(s010):
        kill Z(s0100) with condition 7 = "L(w)"
      kill Z(s0101):
        kill Z(s01010) with condition 1965 = "L(fwFwFWFFFWfWfwwww)"
      kill Z(s01011):
        kill Z(s010110) with condition 1929
```

kill $Z(s010110)$ with condition 1929
 kill $Z(s011)$ with condition 1996 = “L(FwFwFWFWfWFWFwFwfw)”
 omit $Z(s1)$
 as shown in figure 5.1.

$Z(s1)$ is ignored, so the checker would indicate this omission in its report. In fact, $Z(s1)$ is omitted entirely, since it is one of the 11 exceptional boxes.

The use of condition “L(w)” so deep in the tree is unusual. In this case, it’s because the manifold in the exceptional sub-box has $\text{length}(f) = \text{length}(w)$, so that the program will frequently come to places where it can bound $\text{length}(f) > \text{length}(w)$ nearby.

One might wonder why the checker subdivides $Z(s01011)$, since it’s going to use the same condition to kill both halves. The reason is the error bound for $Z(s01011)$ wasn’t good enough to prove that the sub-box is killed directly.

The binary numbers used by the computer require too much space to print. In the example calculation which follows, we instead use a decimal representation. Also, only 10 decimals are printed, less accurate than the 53 binary digits used for the actual calculations.

The sub-box $Z(s01011)$ is the region where

$$\left(\begin{array}{l} -1.381589027741 \dots \leq \text{Re}(L') \leq -1.379848991182 \dots \\ -1.378124546093 \dots \leq \text{Re}(D') \leq -1.376574349753 \dots \\ 0.999893182771 \dots \leq \text{Re}(R') \leq 1.001274250703 \dots \\ -2.535837191243 \dots \leq \text{Im}(L') \leq -2.534606799593 \dots \\ 2.535404997792 \dots \leq \text{Im}(D') \leq -2.534308843448 \dots \\ -0.001953125000 \dots \leq \text{Im}(R') \leq 0.000000000000 \dots \end{array} \right)$$

At this point, we would like to compute

$$f, w, g = f^{-1}wf^{-1}w^{-1}f^{-1}w^{-1}fw^{-1}f^{-1}w^{-1}f^{-1}wf^{-1}wfw, \text{length}(g),$$

and so on. However, these items take on values over an entire sub-box and thus are computed via AffApprox’s (first-order Taylor Approximations with remainder bounds), which are not formally defined until the next Chapter. As such, we complete Example 5.4 at the end of Chapter 6.

Chapter 6: Affine Approximations

Remark 6.1: To show that a sub-box of the parameter box $\mathcal{W}$ is killed by one of the interesting conditions (plus associated killerword) we need to show that at each point in the sub-box, the killerword evaluated at that point satisfies the given condition. That is, we are simply analyzing a certain function from the sub-box to $\mathbf{C}$.

As described in Remark 6.5, this analysis can be pulled back from the sub-box in question to the unit complex 3-disc A , where $A = \{(z_0, z_1, z_2) \in \mathbf{C}^3 : |z_k| \leq 1 \text{ for } k = 1, 2, 3\}$. Loosely, we will analyze such a function on A by using Taylor series approximations consisting of an affine approximating function together with a bound on the “error” in the approximation (this could also be described as a “remainder bound”).

Figure 5.1: six levels of subdivision, in two projections, with all the trimmings

Problems 6.2: There are two immediate problems likely to arise from this Taylor approximation approach. The first problem is the appearance of unpleasant functions such as $\cosh^{-1}$. We have already taken care of this problem by “exponentiating” our preliminary parameter space $\mathcal{P}$. This resulted in all functions under consideration being built up from the co-ordinate functions $L', D',$ and R' on $\mathcal{P}$ by means of the elementary operations $+, -, \times, /$, $\sqrt{}$.

Second, for a given “built-up function” the computer needs to be able to compute the Taylor approximation, and the error term. This will be handled in this section by developing combination formulas for elementary operations (see the Propositions below). Specifically, given two Taylor approximations with error terms representing functions g and h and an elementary operation on g and h , we will show how to get the Taylor approximation with error term for the resultant function from the two original Taylor approximations.

Remark 6.3: We set up the Taylor approximation approach rigorously as follows. The notation will be a bit unusual, but we are motivated by a desire to stay close to the notation used in the checker computer programs, *verify* and *fudging*. However, it should be pointed out that the formulas in this Chapter will be superseded by the ones in Chapter 8, which incorporate a round-off error analysis. It is the Chapter 8 formulas that are used in *verify* and *fudging*.

Definition 6.4: An *AffApprox* x is a five-tuple $(x.f; x.f_0, x.f_1, x.f_2; x.e)$, consisting of four complex numbers $x.f, x.f_0, x.f_1, x.f_2$ and one real number $x.e$, which represents all functions $g : A \rightarrow \mathbf{C}$ such that

$$|g(z_0, z_1, z_2) - (x.f + x.f_0 z_0 + x.f_1 z_1 + x.f_2 z_2)| < x.e$$

for all $(z_0, z_1, z_2) \in A$. That is, x represents all functions from A to $\mathbf{C}$ that are $x.e$ -well-approximated by the affine function $x.f + x.f_0 z_0 + x.f_1 z_1 + x.f_2 z_2$. We will denote this set of functions associated with x by $r(x)$.

Remark 6.5: As mentioned in Remark 6.1, given a sub-box to analyze, instead of working with functions defined on the sub-box, we will work with corresponding functions defined on A . Specifically, rather than build up a function by elementary operations performed on the co-ordinate functions L', D', R' restricted to the given sub-box, we will perform the elementary operations on the following functions defined on A ,

$$(p_0 + ip_3; s_0 + is_3, 0, 0; 0) \quad (p_1 + ip_4; 0, s_1 + is_4, 0; 0) \quad (p_2 + ip_5; 0, 0, s_2 + is_5; 0)$$

where $(p_0 + ip_3, p_1 + ip_4, p_2 + ip_5)$ is the center of the sub-box in question, and the s_i describe the six dimensions of the box. In the computer programs, these three functions are called *along*, *ortho*, and *whirle*, respectively, and p_i and s_i are denoted $pos[i]$ and $size[i]$, respectively.

After the following Remarks, we state and prove the combination formulas.

Remarks 6.6: i) We will break with the convention used previously in this paper and start the numbering of the Propositions with 6.1. However, we will end this Chapter with Example 6.7.

ii) The negation of a set of functions is the set consisting of the negatives of the original functions, and similarly for other operations.

Proposition 6.1 (unary minus): If x is the AffApprox $(x.f; x.f_0, x.f_1, x.f_2; x.e)$ then $-(r(x)) = r(-x)$ where

$$-x = (-x.f; -x.f_0, -x.f_1, -x.f_2; x.e).$$

Proof:

$$|g(z_0, z_1, z_2) - (x.f + x.f_0 z_0 + x.f_1 z_1 + x.f_2 z_2)| < e$$

if and only if

$$|-g(z_0, z_1, z_2) - (-x.f - x.f_0 z_0 - x.f_1 z_1 - x.f_2 z_2)| < e$$

■

Proposition 6.2 (addition): If x is the AffApprox $(x.f; x.f_0, x.f_1, x.f_2; x.e)$ and y is the AffApprox $(y.f; y.f_0, y.f_1, y.f_2; y.e)$, then $r(x + y) \supseteq r(x) + r(y)$, where

$$x + y = (x.f + y.f; x.f_0 + y.f_0, x.f_1 + y.f_1, x.f_2 + y.f_2; x.e + y.e)$$

Proof: If $g \in r(x)$ and $h \in r(y)$ then we must show that $g + h \in r(x + y)$.

$$\begin{aligned} & |(g + h)(z_0, z_1, z_2) - ((x.f + y.f) + (x.f_0 + y.f_0)z_0 + (x.f_1 + y.f_1)z_1 + (x.f_2 + y.f_2)z_2)| \\ & \leq |g(z_0, z_1, z_2) - (x.f + (x.f_0)z_0 + (x.f_1)z_1 + (x.f_2)z_2)| + \\ & \quad |h(z_0, z_1, z_2) - (y.f + (y.f_0)z_0 + (y.f_1)z_1 + (y.f_2)z_2)| \\ & \leq |g(z_0, z_1, z_2) - (x.f + (x.f_0)z_0 + (x.f_1)z_1 + (x.f_2)z_2)| + \\ & \quad |h(z_0, z_1, z_2) - (y.f + (y.f_0)z_0 + (y.f_1)z_1 + (y.f_2)z_2)| \\ & \leq x.e + y.e \end{aligned}$$

■

We now do subtraction. The statement and proof are essentially the same as for addition. The only thing to note is that the errors add.

Proposition 6.3 (subtraction): If x is the AffApprox $(x.f; x.f_0, x.f_1, x.f_2; x.e)$ and y is the AffApprox $(y.f; y.f_0, y.f_1, y.f_2; y.e)$, then $r(x - y) \supseteq r(x) - r(y)$, where

$$x - y = (x.f - y.f; x.f_0 - y.f_0, x.f_1 - y.f_1, x.f_2 - y.f_2; x.e + y.e)$$

■

We now state variations on Propositions 6.2 and 6.3 whose usefulness will not be apparent until Chapter 8, when we incorporate round-off error into these formulas. In what follows, a “double” corresponds to a real number, and has an associated `AffApprox`, with last four entries zero.

Proposition 6.4 (addition of an `AffApprox` and a double): If x is the `AffApprox` $(x.f; x.f_0, x.f_1, x.f_2; x.e)$ and y is a double, then $r(x + y) \supseteq r(x) + r(y)$, where

$$x + y = (x.f + y; x.f_0, x.f_1, x.f_2; x.e).$$

■

Proposition 6.5 (subtraction of a double from an `AffApprox`): If x is the `AffApprox` $(x.f; x.f_0, x.f_1, x.f_2; x.e)$ and y is a double, then $r(x - y) \supseteq r(x) - r(y)$, where

$$x - y = (x.f - y; x.f_0, x.f_1, x.f_2; x.e).$$

■

Proposition 6.6 (multiplication): If x is the `AffApprox` $(x.f; x.f_0, x.f_1, x.f_2; x.e)$ and y is the `AffApprox` $(y.f; y.f_0, y.f_1, y.f_2; y.e)$, then $r(x \times y) \supseteq r(x) \times r(y)$, where

$$\begin{aligned} x \times y = & (x.f \times y.f; x.f \times y.f_0 + x.f_0 \times y.f, x.f \times y.f_1 + x.f_1 \times y.f, x.f \times y.f_2 + x.f_2 \times y.f; \\ & (size(x) + x.e) \times (size(y) + y.e) + (|x.f| \times y.e + x.e \times |y.f|)) \end{aligned}$$

with $size(x) = |x.f_0| + |x.f_1| + |x.f_2|$ and $size(y) = |y.f_0| + |y.f_1| + |y.f_2|$

Proof: If $g \in r(x)$ and $h \in r(y)$ then we must show that $g \times h \in r(x \times y)$. That is, we need to show

$$\begin{aligned} & |(g \times h)(z_0, z_1, z_2) - ((x.f \times y.f) + \\ & (x.f \times y.f_0 + x.f_0 \times y.f)z_0 + (x.f \times y.f_1 + x.f_1 \times y.f)z_1 + (x.f \times y.f_2 + x.f_2 \times y.f)z_2)| \\ & \leq (size(x) + x.e) \times (size(y) + y.e) + (|x.f| \times y.e + x.e \times |y.f|) \end{aligned}$$

Note that for any point $(z_0, z_1, z_2) \in A$ and any functions $g \in r(x)$ and $h \in r(y)$ we can find complex numbers u, v with $|u| \leq 1$ and $|v| \leq 1$, such that

$$g(z_0, z_1, z_2) = x.f + (x.f_0 z_0 + x.f_1 z_1 + x.f_2 z_2) + (x.e)u$$

and

$$h(z_0, z_1, z_2) = y.f + (y.f_0 z_0 + y.f_1 z_1 + y.f_2 z_2) + (y.e)v.$$

Multiplying out, we see that

$$\begin{aligned}
 (g \times h)(z_0, z_1, z_2) &= (x.f \times y.f) + \\
 &+ (x.f \times y.f_0 + x.f_0 \times y.f)z_0 + (x.f \times y.f_1 + x.f_1 \times y.f)z_1 + (x.f \times y.f_2 + x.f_2 \times y.f)z_2 + \\
 &+ (x.f \times y.e)v + (x.e \times y.f)u + \\
 &+ ((x.f_0z_0 + x.f_1z_1 + x.f_2z_2) + (x.e)u) \times ((y.f_0z_0 + y.f_1z_1 + y.f_2z_2) + (y.e)v)
 \end{aligned}$$

Hence,

$$\begin{aligned}
 &|(g \times h)(z_0, z_1, z_2) - ((x.f \times y.f) + \\
 &+ ((x.f \times y.f_0 + x.f_0 \times y.f)z_0 + (x.f \times y.f_1 + x.f_1 \times y.f)z_1 + (x.f \times y.f_2 + x.f_2 \times y.f)z_2))| \\
 &\leq (|x.f|y.e + x.e|y.f|) + (size(x) + x.e) \times (size(y) + y.e).
 \end{aligned}$$

■

Proposition 6.7 (an AffApprox multiplied by a double): If x is the AffApprox $(x.f; x.f_0, x.f_1, x.f_2; x.e)$ and y is a double, then $r(x \times y) \supseteq r(x) \times r(y)$, where

$$x \times y = (x.f \times y; x.f_0 \times y, x.f_1 \times y, x.f_2 \times y; x.e \times |y|)$$

■

Proposition 6.8 (division): If x is the AffApprox $(x.f; x.f_0, x.f_1, x.f_2; x.e)$ and y is the AffApprox $(y.f; y.f_0, y.f_1, y.f_2; y.e)$, then $r(x/y) \supseteq r(x)/r(y)$, where

$$\begin{aligned}
 x/y &= (x.f/y.f; (-x.f \times y.f_0 + x.f_0 \times y.f)/(y.f^2), (-x.f \times y.f_1 + x.f_1 \times y.f)/(y.f^2), \\
 &+ (-x.f \times y.f_2 + x.f_2 \times y.f)/(y.f^2); \\
 &+ (|x.f| + size(x) + x.e)/(|y.f| - (size(y) + y.e)) - \\
 &+ ((|x.f|/|y.f| + size(x)/|y.f|) + |x.f|size(y)/(|y.f||y.f|)))
 \end{aligned}$$

Of course, we have to avoid division by zero. That is, we demand that $|y.f| > size(y) + y.e$.

Proof: For notational convenience, denote $(x.f_0z_0 + x.f_1z_1 + x.f_2z_2)$ by $x.f_kz_k$ and similarly for $y.f_kz_k$ and so on. As above, note that for any point $(z_0, z_1, z_2) \in A$ and any functions $g \in r(x)$ and $h \in r(y)$ we can find complex numbers u, v with $|u| \leq 1$ and $|v| \leq 1$, such that

$$g(z_0, z_1, z_2) = x.f + (x.f_kz_k) + (x.e)u$$

and

$$h(z_0, z_1, z_2) = y.f + (y.f_kz_k) + (y.e)v.$$

We compare $(g/h)(z_0, z_1, z_2)$ with its putative affine approximation. That is, we analyze

$$\begin{aligned}
 &|(x.f + (x.f_kz_k) + (x.e)u)/(y.f + (y.f_kz_k) + (y.e)v) - \\
 &((x.f/y.f) + \frac{(x.f_k)y.f - x.f(y.f_k)}{y.f^2}z_k)|
 \end{aligned}$$

Putting this over a common denominator of $|(y.f^2)(y.f + (y.f_k z_k) + (y.e)v)|$ and cancelling equal terms (in the numerator) we are left with a quotient whose numerator is

$$|x.e(y.f^2)u - (x.f_k)y.f(y.f_k)z_k - x.f(y.f_k^2)z_k + (x.f)y.f(y.e)v + x.f_k(y.f)y.e(v)z_k - x.f(y.f_k)y.e(v)z_k|.$$

We must show this (first) quotient is bounded by

$$(|x.f| + size(x) + x.e)/(|y.f| - (size(y) + y.e)) - ((|x.f|/|y.f| + size(x)/|y.f|) + |x.f|size(y)/(|y.f||y.f|)).$$

Putting this over a common denominator of $|y.f|^2(|y.f| - (size(y) + y.e))$ and cancelling equal terms (in the numerator) we are left with a second quotient, whose numerator is

$$x.e|y.f|^2 - (-|x.f||y.f|y.e - size(x)|y.f|(size(y) + y.e) - |x.f|size(y)(size(y) + y.e))$$

and we see that all terms in this numerator are positive. Further, the terms in the numerators of the first and second quotients correspond in a natural way, and each term in the numerator of the second quotient is greater than or equal to the absolute value of its corresponding term in the numerator of the first quotient.

Finally, because the denominator in the second quotient is less than or equal to the absolute value of the denominator in the first quotient, we see that the absolute value of the first quotient is less than or equal to the second quotient, as desired. ■

We present a couple of variations on Proposition 6.8 which will be useful when we do round-off error.

Proposition 6.9 (division of a double by an AffApprox): If x is a double and y is the AffApprox $(y.f; y.f_0, y.f_1, y.f_2; y.e)$, then $r(x/y) \supseteq r(x)/r(y)$, where

$$x/y = (x/y.f; -x \times y.f_0/(y.f^2), -x.f \times y.f_1/(y.f^2), -x.f \times y.f_2/(y.f^2); (|x|/(|y.f| - (size(y) + y.e)) - (|x|/|y.f| + |x|size(y)/(|y.f||y.f|)))$$

Of course, we have to avoid division by zero. That is, we demand that $|y.f| > size(y) + y.e$. ■

Proposition 6.10 (division of an AffApprox by a double): If x is the AffApprox $(x.f; x.f_0, x.f_1, x.f_2; x.e)$ and y is a double, then $r(x/y) \supseteq r(x)/r(y)$, where

$$x/y = (x.f/y; x.f_0/y, x.f_1/y, x.f_2/y; x.e/|y|)$$

Of course, we have to avoid division by zero. That is, we demand that $|y| > 0$. ■

Finally, we do the square root.

Proposition 6.11 (square root): If x is the AffApprox $(x.f; x.f_0, x.f_1, x.f_2; x.e)$ then $r(\sqrt{x}) \supseteq \sqrt{r(x)}$, where

$$\sqrt{x} = (\sqrt{x.f}; \frac{x.f_0}{2\sqrt{x.f}}, \frac{x.f_1}{2\sqrt{x.f}}, \frac{x.f_2}{2\sqrt{x.f}}; \sqrt{|x.f|} - (\frac{\text{size}(x)}{2\sqrt{|x.f|}} + \sqrt{|x.f| - (\text{size}(x) + x.e)}))$$

Of course, we have to avoid division by zero, and taking the real square root of a negative number. In particular, when $|x.f| > \text{size}(x) + x.e$ we get the formula above, but if this does not hold, then we use the crude estimate $(0; 0, 0, 0; \sqrt{|x.f| + \text{size}(x) + x.e})$.

Proof: As above, note that for any point $(z_0, z_1, z_2) \in A$ and any function $g \in r(x)$ we can find a complex number u with $|u| \leq 1$, such that

$$g(z_0, z_1, z_2) = x.f + (x.f_k z_k) + (x.e)u.$$

Also, because $|x.f| > \text{size}(x) + x.e$ we see that the argument of $x.f + (x.f_k z_k) + (x.e)u$ is within $\pi/2$ of the argument of $x.f$, and therefore, we can require that $\sqrt{g(z_0, z_1, z_2)}$ has argument within $\pi/4$ of the argument of $\sqrt{x.f}$.

We need to show that

$$\begin{aligned} & |\sqrt{x.f + x.f_k z_k + (x.e)u} - (\sqrt{x.f} + \frac{x.f_k}{2\sqrt{x.f}})z_k| \\ & \leq \sqrt{|x.f|} - (\frac{\text{size}(x)}{2\sqrt{|x.f|}} + \sqrt{|x.f| - (\text{size}(x) + x.e)}) \end{aligned}$$

Or, after multiplying both sides by $\sqrt{|x.f|}$,

$$\begin{aligned} & \sqrt{x.f(x.f + x.f_k z_k + (x.e)u)} - (x.f + (x.f_k)z_k/2) \\ & \leq (|x.f| - \text{size}(x)/2) - \sqrt{|x.f|(|x.f| - (\text{size}(x) + x.e))} \end{aligned}$$

The two sides of the inequality are of the form $A - B$ and $C - D$, and we “simplify” by multiplying by $\frac{A+B}{A+B}$ and $\frac{C+D}{C+D}$. We now show that the (absolute value of the) left-hand numerator is less than or equal to the right-hand numerator. Later, we will show that the (absolute value of the) left-hand denominator is larger than or equal to the right-hand denominator. The left-hand numerator is

$$\begin{aligned} & |x.f(x.f + x.f_k z_k + (x.e)u) - (x.f + (x.f_k)z_k/2)^2| \\ & = |x.f^2 + x.f(x.f_k)z_k + x.f(x.e)u - x.f^2 - x.f(x.f_k)z_k - (x.f_k^2)z_k^2/4| \\ & = |x.f(x.e)u - (x.f_k^2)z_k^2/4| \end{aligned}$$

The right-hand numerator is

$$\begin{aligned}
 & (|x.f| - \text{size}(x)/2)^2 - |x.f|(|x.f| - (\text{size}(x) + x.e)) \\
 &= |x.f|^2 - |x.f|\text{size}(x) + \text{size}(x)^2/4 - |x.f|^2 + |x.f|\text{size}(x) + |x.f|x.e \\
 &= |x.f|x.e + \text{size}(x)^2/4
 \end{aligned}$$

So the left-hand numerator is indeed less than or equal to the right-hand numerator.

We now compare the denominators, but only after dividing each by $\sqrt{|x.f|}$. The left-hand denominator is

$$|\sqrt{x.f + x.f_k z_k + (x.e)u} + (\sqrt{x.f} + \frac{x.f_k z_k}{2\sqrt{x.f}})|$$

while the right-hand denominator is

$$\sqrt{|x.f|} - \frac{\text{size}(x)}{2\sqrt{|x.f|}} + \sqrt{|x.f| - (\text{size}(x) + x.e)}$$

The claim that the left-hand denominator is greater than or equal to the right-hand denominator is a bit complicated. First, compare the $\sqrt{x.f}$ term and the $\sqrt{|x.f|}$ terms. They are the same distance from the origin. Next, note that as z_k and u take on all values, $x.f + x.f_k z_k + (x.e)u$ describes a disk centered at $x.f$ and whose radius is less than $|\sqrt{x.f}|$. Hence, $\sqrt{x.f + x.f_k z_k + (x.e)u}$ describes a convex symmetric (about the line formed by the origin and $x.f$) set centered at $\sqrt{x.f}$. Further, $\sqrt{x.f} + \sqrt{x.f + x.f_k z_k + (x.e)u}$ describes a convex symmetric (about the line formed by the origin and $x.f$) set centered at $2\sqrt{x.f}$. In any case, it is easy enough to see that no points on this convex symmetric set get closer to the origin than $\sqrt{|x.f|} + \sqrt{|x.f| - (\text{size}(x) + x.e)}$.

Finally, because $|\frac{x.f_k z_k}{2\sqrt{x.f}}| \leq \frac{\text{size}(x)}{2\sqrt{|x.f|}}$, no points of

$$\sqrt{x.f} + \sqrt{x.f + x.f_k z_k + (x.e)u} + \frac{x.f_k z_k}{2\sqrt{x.f}}$$

can get closer to the origin than

$$\sqrt{|x.f|} + \sqrt{|x.f| - (\text{size}(x) + x.e)} - \frac{\text{size}(x)}{2\sqrt{|x.f|}}$$

■

Example 6.7 (Continuation of Example 5.4): We repeat the description of the sub-box under investigation.

The sub-box $Z(s01011)$ with

$$s = 00100011000111011100111100010111111101111100111001111000001111011110111$$

is the region where

$$\begin{pmatrix} -1.381589027741 \dots \leq \operatorname{Re}(L') \leq -1.379848991182 \dots \\ -1.378124546093 \dots \leq \operatorname{Re}(D') \leq -1.376574349753 \dots \\ 0.999893182771 \dots \leq \operatorname{Re}(R') \leq 1.001274250703 \dots \\ -2.535837191243 \dots \leq \operatorname{Im}(L') \leq -2.534606799593 \dots \\ 2.535404997792 \dots \leq \operatorname{Im}(D') \leq -2.534308843448 \dots \\ -0.001953125000 \dots \leq \operatorname{Im}(R') \leq 0.000000000000 \dots \end{pmatrix}$$

For this sub-box, we get

$$f = \begin{bmatrix} \begin{pmatrix} -0.8677851121 + i1.4607429651; \\ 0.0000248810 - i0.0003125810, \\ 0.0000000000 + i0.0000000000, \\ 0.0000000000 + i0.0000000000; \\ 0.0000000289 \end{pmatrix} & \begin{pmatrix} 0.0000000000 + i0.0000000000; \\ 0.0000000000 + i0.0000000000, \\ 0.0000000000 + i0.0000000000, \\ 0.0000000000 + i0.0000000000; \\ 0.0000000000 \end{pmatrix} \\ \begin{pmatrix} 0.0000000000 + i0.0000000000; \\ 0.0000000000 + i0.0000000000, \\ 0.0000000000 + i0.0000000000, \\ 0.0000000000 + i0.0000000000; \\ 0.0000000000 \end{pmatrix} & \begin{pmatrix} -0.3006023265 - i0.5060039953; \\ -0.0000909686 - i0.0000593570, \\ 0.0000000000 + i0.0000000000, \\ 0.0000000000 + i0.0000000000; \\ 0.0000000301 \end{pmatrix} \end{bmatrix}$$

and

$$w = \begin{bmatrix} \begin{pmatrix} -0.5845111829 + i0.4773282853; \\ 0.0000000000 + i0.0000000000, \\ -0.0000296707 - i0.0001657332, \\ -0.0004345111 - i0.0001209539; \\ 0.0000002590 \end{pmatrix} & \begin{pmatrix} -0.2840228472 + i0.9825063583; \\ 0.0000000000 + i0.0000000000, \\ 0.0000516606 - i0.0001128245, \\ 0.0005776611 - i0.0001998632; \\ 0.0000006462 \end{pmatrix} \\ \begin{pmatrix} -0.2832291572 + i0.9833572297; \\ 0.0000000000 + i0.0000000000, \\ 0.0000515806 - i0.0001129408, \\ -0.0005778031 + i0.0002005440; \\ 0.0000002806 \end{pmatrix} & \begin{pmatrix} -0.5846352333 + i0.4764792236; \\ 0.0000000000 + i0.0000000000, \\ -0.0000294917 - i0.0001656653, \\ 0.0004341392 + i0.0001213070; \\ 0.0000005286 \end{pmatrix} \end{bmatrix}.$$

calculating $g = f^{-1}wf^{-1}w^{-1}f^{-1}w^{-1}fw^{-1}f^{-1}w^{-1}f^{-1}wf^{-1}wfw$ gives

$$g = \begin{bmatrix} \begin{pmatrix} -0.5764337542 + i0.4752708071; \\ -0.0031657223 - i0.0001436786, \\ -0.0017723577 + i0.0000352928, \\ -0.0011623491 + i0.0017516088; \\ 0.0008229225 \end{pmatrix} & \begin{pmatrix} -0.2704033973 + i0.9822741250; \\ -0.0045902952 - i0.0019135041, \\ -0.0026219461 - i0.0007506230, \\ -0.0002823450 + i0.0033805602; \\ 0.0008037640 \end{pmatrix} \\ \begin{pmatrix} -0.2861207992 + i0.9766064999; \\ -0.0002777968 + i0.0020330488, \\ 0.0000837571 + i0.0010241875, \\ 0.0028322367 - i0.0005972336; \\ 0.0018172437 \end{pmatrix} & \begin{pmatrix} -0.5861133046 + i0.4624368851; \\ -0.0021932627 + i0.0040523411, \\ -0.0008612361 + i0.0022394639, \\ 0.0061581377 - i0.0005862070; \\ 0.0017738513 \end{pmatrix} \end{bmatrix}.$$

We then get

$$\text{length}(g) = \begin{pmatrix} -1.3588762105 - i2.4897230182; \\ 0.0030210500 - i0.0182284729, \\ 0.0007938572 - i0.0096614614, \\ -0.0122034521 + i0.0074353043; \\ 0.0080071969 \end{pmatrix}$$

and

$$\frac{\text{length}(g)}{L'} = \begin{pmatrix} 0.9825397896 - i0.0008933519; \\ 0.0053701602 + i0.0037789019, \\ 0.0028076072 + i0.0018421952, \\ -0.0002400615 - i0.0049443045; \\ 0.0027802966 \end{pmatrix}.$$

This isn't quite good enough to kill the sub-box, since $|\text{length}(g)/L'|$ can be high as 1.0001951323.

When we subdivide $Z(s01011)$, we have to analyze two sub-boxes, $Z(s010110)$ and $Z(s010111)$. For $Z(s010110)$, the same calculation on the region

$$\begin{aligned} -1.381589027741073400 &\leq \text{Re}(L') \leq -1.379848991182205200 \\ -1.378124546093485700 &\leq \text{Re}(D') \leq -1.376574349753672900 \\ 0.999893182771602220 &\leq \text{Re}(R') \leq 1.001274250703607400 \\ -2.535837191243490300 &\leq \text{Im}(L') \leq -2.534606799593201600 \\ -2.535404997792558600 &\leq \text{Im}(D') \leq -2.534308843448505900 \\ -0.001953125000000000 &\leq \text{Im}(R') \leq -0.000976562500000000 \end{aligned}$$

gives

$$\frac{\text{length}(g)}{L'} = \begin{pmatrix} 0.9814518667 + i0.0008103446; \\ 0.0053616729 + i0.0037834001, \\ 0.0028027236 + i0.0018435245, \\ -0.0013175066 - i0.0032448794; \\ 0.0019033926 \end{pmatrix},$$

and we can then bound $|\frac{\text{length}(g)}{L'}| \leq 0.9967745579$, which kills $Z(s010110)$.

On $Z(s010111)$, the calculation gives

$$\frac{\text{length}(g)}{L'} = \begin{pmatrix} 0.9836225919 - i0.0025990177; \\ 0.0053786346 + i0.0037743930, \\ 0.0028124892 + i0.0018408583, \\ -0.0013333182 - i0.0032343347; \\ 0.0019044429 \end{pmatrix}$$

and $|\frac{\text{length}(g)}{L'}| \leq 0.9989610507$, which kills $Z(s010111)$.

Chapter 7: Complex Numbers with Round-Off Error

Remark 7.1: The theoretical method for proving Theorem 0.2 has been implemented on the computer programs *verify* and *fudging* given in the Appendices. To make this computer-aided proof rigorous, we need to deal with round-off error in calculations.

One approach to round-off error would be to use interval arithmetic packages to carry out all calculations with floating-point numbers (also called “doubles”), or to generate our own version of these packages. However, it appears that this would be much too slow given the size of our collection of sub-boxes and conditions and killer words.

To solve this problem of speed, we implement round-off error at a higher level of programming. That is, we incorporate round-off error directly into AffApprox’s. This necessitates that we incorporate it into complex numbers as well.

Definition 7.2: In the next Chapter we work with AffApprox’s. In this section we show how to do standard operations on complex numbers while keeping track of round-off error. There are two types of complex numbers to consider:

1.) An *XComplex* corresponds to a complex number that is represented exactly. Thus, it simply consists of a real part and an imaginary part.

2.) An *AComplex* corresponds to an “interval” that contains the complex number in question. Thus, it consists of an XComplex and a floating-point number representing the error. In particular, $(x; e)$ represents the set of complex numbers $\{w : |w - x| \leq e\}$. Following the notation of Chapter 6, we could now denote this set of complex numbers by $r(x, e)$, but instead we suppress mention of the r functions throughout the rest of this section. It seems preferable to abuse notation in this fashion in the interests of simplicity.

Remark 7.3: In general, our operations act on XComplexes and produce AComplexes, or they act on AComplexes and produce AComplexes. In one case, the unary minus, an XComplex goes to an XComplex. In the calculations that follow the effect on the error is the whole point.

Conventions 7.4: We begin, by writing down our basic rules, which follow easily from the IEEE-754 double-precision standard for machine arithmetic. (Actually, the “hypot” function $h(a, b)$, which computes by elaborate chicanery $\sqrt{a^2 + b^2}$, is not part of the IEEE standard, but satisfies the appropriate standard according to the documentation provided (see [Kahan]).) The operations here are on double-precision floating-point real numbers (doubles) and we denote a true operation by the usual symbol and the associated machine operation by the same symbol in a circle, with two exceptions: a machine square root $\sqrt{a}$ is denoted $\sqrt[a]{a}$ and the machine version of the hypot function is denoted $h_{\circ}$. Perhaps a third exception is our occasional notation of true multiplication by the absence of a symbol. The standard number used in error analysis is an “EPS.” It depends on the number of bits used to store floating-point numbers, and this can vary from machine to machine. Finally, it should be noted that our analysis breaks down when there is “underflow,” so in the computer programs we ask the computer to inform us if underflow has occurred.

As in Chapter 6, we now break with the usual numbering convention.

Basic Properties 7.0 (assuming no underflow):

$1 + k \times EPS = 1 \oplus (k \otimes EPS)$ when k is an integer which is not huge in absolute value.

$2^k \times A = 2^k \otimes A$ when k is an integer, $2^k \otimes A$ is not infinity.

$$\begin{aligned}
 |(a+b) - (a \oplus b)| &\leq (EPS/2)|a+b| \\
 |(a+b) - (a \oplus b)| &\leq (EPS/2)|a \oplus b| \\
 |(a-b) - (a \ominus b)| &\leq (EPS/2)|a-b| \\
 |(a-b) - (a \ominus b)| &\leq (EPS/2)|a \ominus b| \\
 |(a \times b) - (a \otimes b)| &\leq (EPS/2)|a \times b| \\
 |(a \times b) - (a \otimes b)| &\leq (EPS/2)|a \otimes b| \\
 |(a/b) - (a \oslash b)| &\leq (EPS/2)|a/b| \\
 |(a/b) - (a \oslash b)| &\leq (EPS/2)|a \oslash b| \\
 |\sqrt{a} - \sqrt[3]{a}| &\leq (EPS/2)|\sqrt{a}| \\
 |\sqrt{a} - \sqrt[3]{a}| &\leq (EPS/2)|\sqrt[3]{a}| \\
 |h(a,b) - h_{\circ}(a,b)| &\leq (EPS)|h(a,b)| \\
 |h(a,b) - h_{\circ}(a,b)| &\leq (EPS)|h_{\circ}(a,b)|
 \end{aligned}$$

From these formulas, we immediately compute the following.

$$\begin{aligned}
 (1 - EPS/2)|a+b| &\leq |a \oplus b| \leq (1 + EPS/2)|a+b| \\
 (1 - EPS/2)|a \oplus b| &\leq |a+b| \leq (1 + EPS/2)|a \oplus b| \\
 (1 - EPS/2)|a-b| &\leq |a \ominus b| \leq (1 + EPS/2)|a-b| \\
 (1 - EPS/2)|a \ominus b| &\leq |a-b| \leq (1 + EPS/2)|a \ominus b| \\
 (1 - EPS/2)|a \times b| &\leq |a \otimes b| \leq (1 + EPS/2)|a \times b| \\
 (1 - EPS/2)|a \otimes b| &\leq |a \times b| \leq (1 + EPS/2)|a \otimes b| \\
 (1 - EPS/2)|a/b| &\leq |a \oslash b| \leq (1 + EPS/2)|a/b| \\
 (1 - EPS/2)|a \oslash b| &\leq |a/b| \leq (1 + EPS/2)|a \oslash b| \\
 (1 - EPS/2)|\sqrt{a}| &\leq |\sqrt[3]{a}| \leq (1 + EPS/2)|\sqrt{a}| \\
 (1 - EPS/2)|\sqrt[3]{a}| &\leq |\sqrt{a}| \leq (1 + EPS/2)|\sqrt[3]{a}| \\
 (1 - EPS)|h(a,b)| &\leq |h_{\circ}(a,b)| \leq (1 + EPS)|h(a,b)| \\
 (1 - EPS)|h_{\circ}(a,b)| &\leq |h(a,b)| \leq (1 + EPS)|h_{\circ}(a,b)|
 \end{aligned}$$

Of course, we can also get the following type of formula, which is sometimes convenient, for example, in the proof of Lemma 7.2.

$$\left(\frac{1}{1 + \frac{EPS}{2}}\right)|a \oplus b| \leq |a + b| \leq \left(\frac{1}{1 - \frac{EPS}{2}}\right)|a \oplus b|$$

Proof: There is a finite set of numbers which are representable on the computer, and the IEEE standard states that the result of an operation is always the closest representable number to the true solution. Ignoring technicalities, a non-zero floating-point number is represented by a fixed number of bits of which the first determines the sign of the number, the next m represent the exponent, and the remaining n represent the mantissa of the number. Because our non-zero numbers start with a 1, that means the n mantissa bits actually represent the next n binary digits after the 1. That is, the mantissa is actually $1.b_1b_2b_3\dots b_n$. With this divvying up of the $m + n + 1$ bits among exponent and mantissa, EPS would be 2^{-n} and $EPS/2$ would be $2^{-(n+1)}$.

Given this set-up, properties of the form

$$|(a + b) - (a \oplus b)| \leq (EPS/2)|a + b|$$

follow immediately. Then,

$$|(a + b) - (a \oplus b)| \leq (EPS/2)|a \oplus b|$$

follows because the true answer has “exponent” which is less than or equal to the exponent of the machine answer. ■

Before starting in with our Propositions, we prove a couple of lemmas.

Lemma 7.0:

$$(1 - EPS) \otimes |a \oplus b| \leq |a + b| \leq (1 + EPS) \otimes |a \oplus b|$$

Analagous formulas hold for $-$, $$, $/$, $\sqrt{}$.*

Proof: Assume $a + b > 0$. If $(1 + EPS) \otimes (a \oplus b) < (a + b)$ then the machine number $(1 + EPS) \otimes (a \oplus b)$ is a better approximation to $a + b$ than $a \oplus b$, because $(a \oplus b) < (1 + EPS) \otimes (a \oplus b)$. This contradicts the IEEE standard. The case $a + b < 0$ can be handled similarly, and the case $a + b = 0$ is trivial. Similarly for the left-hand inequality. ■

Lemma 7.1:

$$(1 + EPS/2)^a A \leq (1 + kEPS) \otimes A$$

where $A \geq 0$, and a and k are (not huge) integers, such that for a even, $k = \frac{a}{2} + 1$ and for a odd, $k = \frac{a+1}{2} + 1$.

Proof:

$$(1 + EPS/2)^a A \leq (1 - EPS/2)(1 + kEPS)A \leq (1 + kEPS) \otimes A$$

The first inequality holds if a and k are as in the Lemma, and the second inequality is a consequence of one of the formulas preceding Lemma 7.0 ($A \geq 0$). ■

We start the operations. We will give proofs for most, the others should be straightforward to derive. Note that for an XComplex, $x = (x.re, x.im)$, and for an AComplex, $x = (x.re, x.im, x.e)$.

Proposition 7.1 (-X):

$$-x = (-x.re, -x.im). \quad \blacksquare$$

Proposition 7.2 (X + D) (an XComplex and a double added together, which yields an AComplex):

$$x + d = (x.re \oplus d, x.im; (EPS/2) \otimes |x.re \oplus d|)$$

Proof: The error is bounded by

$$\begin{aligned} & |(x.re + d) - (x.re \oplus d)| \\ & \leq (EPS/2)|x.re \oplus d| \\ & = (EPS/2) \otimes |x.re \oplus d| \end{aligned}$$

■

Proposition 7.3 (X - D) (a double subtracted from an XComplex, which yields an AComplex):

$$x - d = (x.re \ominus d, x.im; (EPS/2) \otimes |x.re \ominus d|) \quad \blacksquare$$

Proposition 7.4 (X + X) (an XComplex and an XComplex added together, which yields an AComplex):

$$x + y = (x.re \oplus y.re, x.im \oplus y.im; (EPS/2) \otimes ((1 + EPS) \otimes (|x.re \oplus y.re| \oplus |x.im \oplus y.im|)))$$

Proof: The error is bounded by

$$\begin{aligned} & |(x.re + y.re) - (x.re \oplus y.re)| + |(x.im + y.im) - (x.im \oplus y.im)| \\ & \leq (EPS/2)(|x.re \oplus y.re| + |x.im \oplus y.im|) \\ & \leq (EPS/2)((1 + EPS) \otimes (|x.re \oplus y.re| \oplus |x.im \oplus y.im|)) \\ & = (EPS/2) \otimes ((1 + EPS) \otimes (|x.re \oplus y.re| \oplus |x.im \oplus y.im|)) \end{aligned}$$

To go from line 2 to line 3 we used Lemma 7.0. ■

Proposition 7.5 (X - X):

$$x + y = (x.re \ominus y.re, x.im \ominus y.im; (EPS/2) \otimes ((1 + EPS) \otimes (|x.re \ominus y.re| \oplus |x.im \ominus y.im|)))$$

■

Proposition 7.6 (A + A) (an AComplex and an AComplex added together, which yields an AComplex):

$$x + y = (re, im; e) \text{ where}$$

$$re = x.re \oplus y.re$$

$$im = x.im \oplus y.im$$

$$e = (1 + 2EPS) \otimes (((EPS/2) \otimes (|re| \oplus |im|)) \oplus (x.e \oplus y.e))$$

Proof: The error is bounded by the sum of the contributions from the real part, the imaginary part, and the two individual errors:

$$\begin{aligned} & |(x.re \oplus y.re) - (x.re + y.re)| + |(x.im \oplus y.im) - (x.im + y.im)| + (x.e + y.e). \\ & \leq (EPS/2)|x.re \oplus y.re| + (EPS/2)|x.im \oplus y.im| + (1 + EPS/2)(x.e \oplus y.e) \\ & \leq (1 + EPS/2)(EPS/2)(|x.re \oplus y.re| \oplus |x.im \oplus y.im|) + (1 + EPS/2)(x.e \oplus y.e) \\ & = (1 + EPS/2)((EPS/2)(|x.re \oplus y.re| \oplus |x.im \oplus y.im|) + (x.e \oplus y.e)) \\ & \leq (1 + EPS/2)^2(((EPS/2)(|x.re \oplus y.re| \oplus |x.im \oplus y.im|)) \oplus (x.e \oplus y.e)) \\ & \leq (1 + 2EPS) \otimes (((EPS/2) \otimes (|x.re \oplus y.re| \oplus |x.im \oplus y.im|)) \oplus (x.e \oplus y.e)) \end{aligned}$$

■

The hierarchy for machine operations is the same as that for true operations, so one pair of parentheses is unnecessary and will often be omitted in what follows.

Proposition 7.7 (A - A):

$$x + y = (re, im; e) \text{ where}$$

$$re = x.re \ominus y.re$$

$$im = x.im \ominus y.im$$

$$e = (1 + 2EPS) \otimes (((EPS/2) \otimes (|re| \oplus |im|)) \oplus (x.e \oplus y.e))$$

■

Proposition 7.8 (X × D):

$$x \times d = (re, im; e) \text{ where}$$

$$re = x.re \otimes y$$

$$im = x.im \otimes y$$

$$e = (EPS/2) \otimes ((1 + EPS) \otimes (|re| \oplus |im|))$$

Proof: The error is bounded by

$$\begin{aligned} & |(x.re \times y) - (x.re \otimes y)| + |(x.im \times y) - (x.im \otimes y)| \\ & \leq (EPS/2)|x.re \otimes y| + (EPS/2)|x.im \otimes y| \end{aligned}$$

$$\begin{aligned}
 &= (EPS/2)(|x.re \otimes y| + |x.im \otimes y|) \\
 &\leq (EPS/2) \otimes ((1 + EPS) \otimes (|x.re \otimes y| \oplus |x.im \otimes y|))
 \end{aligned}$$

■

Proposition 7.9 (X / D):

$x/d = (re, im; e)$ where

$re = x.re \otimes y$

$im = x.im \otimes y$

$e = (EPS/2) \otimes ((1 + EPS) \otimes (|re| \oplus |im|))$ ■

Proposition 7.10 (X × X):

$x \times y = (re, im; e)$ where

$re = re1 \ominus re2$, with $re1 = x.re \otimes y.re$ and $re2 = x.im \otimes y.im$

$im = im1 \oplus im2$, with $im1 = x.re \otimes y.im$ and $im2 = x.im \otimes y.re$

$e = EPS \otimes ((1 + 2EPS) \otimes (|re1| \oplus |re2|) \oplus (|im1| \oplus |im2|))$

Proof: The error is bounded by the sum of the contributions from the real part and the imaginary part:

$$\begin{aligned}
 &|(x.re \times y.re - x.im \times y.im) - ((x.re \otimes y.re) \ominus (x.im \otimes y.im))| \\
 &\quad + |(x.re \times y.im + x.im \times y.re) - ((x.re \otimes y.re) \oplus (x.im \otimes y.im))|
 \end{aligned}$$

We want to bound this by a machine formula. Let's begin by bounding

$$|(x.re \times y.re - x.im \times y.im) - ((x.re \otimes y.re) \ominus (x.im \otimes y.im))|$$

by a machine formula.

$$\begin{aligned}
 &|(x.re \times y.re - x.im \times y.im) - ((x.re \otimes y.re) \ominus (x.im \otimes y.im))| \\
 &\leq |((x.re \times y.re) - (x.im \times y.im)) - ((x.re \otimes y.re) - (x.im \otimes y.im))| \\
 &\quad + |((x.re \otimes y.re) - (x.im \otimes y.im)) - ((x.re \otimes y.re) \ominus (x.im \otimes y.im))| \\
 &\leq |(x.re \times y.re) - (x.re \otimes y.re)| + |(x.im \times y.im) - (x.im \otimes y.im)| \\
 &\quad + (EPS/2)|((x.re \otimes y.re) - (x.im \otimes y.im))| \\
 &\leq (EPS/2)|((x.re \otimes y.re) - (x.im \otimes y.im))| \\
 &\quad + (EPS/2)(|x.re \otimes y.re| + |x.im \otimes y.im|) \\
 &= (EPS/2)(2)(|x.re \otimes y.re| + |x.im \otimes y.im|)
 \end{aligned}$$

$$\leq EPS(1 + EPS/2)(|x.re \otimes y.re| \oplus |(x.im \otimes y.im)|)$$

Almost the exact same calculation produces the analogous formula for the imaginary contribution, and we now combine the two to get a bound on the total error.

$$\begin{aligned} &\leq EPS(1 + EPS/2)(|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \\ &\quad + EPS(1 + EPS/2)(|x.re \otimes y.im| \oplus |x.im \otimes y.re|) \\ &= EPS(1 + EPS/2)((x.re \otimes y.re| \oplus |x.im \otimes y.im|) \\ &\quad + (|x.re \otimes y.im| \oplus |x.im \otimes y.re|)) \\ &\leq EPS(1 + EPS/2)^2((|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \\ &\quad \oplus (|x.re \otimes y.im| \oplus |x.im \otimes y.re|)) \\ &\leq EPS \otimes ((1 + 2EPS) \otimes ((|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \\ &\quad \oplus (|x.re \otimes y.im| \oplus |x.im \otimes y.re|))) \end{aligned}$$

■

Proposition 7.11 (D / X):

$x/y = (re, im; e)$ where

$re = (x \otimes y.re) \otimes nrm$ where $nrm = y.re \otimes y.re \oplus y.im \otimes y.im$

$im = -(x \otimes y.im) \otimes nrm$

$e = (2EPS) \otimes ((1 + 2EPS) \otimes (|re| \oplus |im|))$

Proof: The true version of x/y is equal to $(x \times y.re + i(-x \times y.im))/(y.re^2 + y.im^2)$ and we need to compare this with the machine version to find the error. Further, this error is less than or equal to the sum of the real error and the imaginary error. Thus, we start with the real calculation (as above, we use nrm to represent the machine version of $y.re^2 + y.im^2$).

$$\begin{aligned} & \left| \frac{x \times y.re}{y.re^2 + y.im^2} - ((x \otimes y.re) \otimes nrm) \right| \\ & \leq |(x \otimes y.re) \otimes nrm - \frac{x \otimes y.re}{nrm}| + \left| \frac{x \otimes y.re}{nrm} - \frac{x \times y.re}{nrm} \right| + \left| \frac{x \times y.re}{nrm} - \frac{x \times y.re}{y.re^2 + y.im^2} \right| \end{aligned}$$

Before continuing, let's compare $\frac{1}{nrm}$ and $\frac{1}{y.re^2 + y.im^2}$ by developing a formula for comparing $\frac{1}{a^2 + b^2}$ and its associated $\frac{1}{nrm}$:

Lemma 7.2:

$$\left| \frac{1}{nrm} - \frac{1}{a^2 + b^2} \right| \leq (EPS + (EPS/2)^2) \frac{1}{nrm}$$

where $nrm = a \otimes a \oplus b \otimes b$.

Proof: We compute that

$$\left(\frac{1}{1+EPS/2}\right)^2 \times nrm \leq a^2 + b^2 \leq \left(\frac{1}{1-EPS/2}\right)^2 \times nrm,$$

hence

$$\frac{1}{nrm}(1-EPS/2)^2 \leq \frac{1}{a^2+b^2} \leq \frac{1}{nrm}(1+EPS/2)^2.$$

It then follows that

$$\begin{aligned} \left| \frac{1}{nrm} - \frac{1}{a^2+b^2} \right| &\leq \frac{1}{nrm}(1+EPS/2)^2 - \frac{1}{nrm} \\ &= \frac{1}{nrm}((1+EPS/2)^2 - 1) = (EPS + (EPS/2)^2) \frac{1}{nrm} \end{aligned}$$

■

Getting back to our main calculation (with $nrm = y.re \otimes y.re \oplus y.im \otimes y.im$),

$$\begin{aligned} &|(x \otimes y.re) \otimes nrm - \frac{x \otimes y.re}{nrm}| + \left| \frac{x \otimes y.re}{nrm} - \frac{x \times y.re}{nrm} \right| + \left| \frac{x \times y.re}{nrm} - \frac{x \times y.re}{y.re^2 + y.im^2} \right| \\ &\leq (EPS/2) \frac{|x \otimes y.re|}{nrm} + (EPS/2) \frac{|x \otimes y.re|}{nrm} + (EPS + (EPS/2)^2) \frac{|x \times y.re|}{nrm} \\ &= (EPS/2) \left(\frac{1}{nrm} \right) (2|x \otimes y.re| + (2 + EPS/2) \times |x \times y.re|) \\ &\leq (EPS/2) \left(\frac{1}{nrm} \right) (2|x \otimes y.re| + (2 + EPS/2)(1 + EPS/2) \times |x \otimes y.re|) \\ &= (EPS/2) \left(\frac{1}{nrm} \right) (|x \otimes y.re|)(2 + (2 + EPS/2)(1 + EPS/2)) \\ &\leq (EPS/2)(4 + 3EPS/2 + (EPS/2)^2)(|x \otimes y.re|) \left(\frac{1}{nrm} \right) \\ &\leq (EPS/2)(4 + 3EPS/2 + (EPS/2)^2)(1 + EPS/2)(|x \otimes y.re| \otimes nrm) \\ &\leq (2EPS)(1 + 3EPS/8 + (EPS/4)^2)(1 + EPS/2)(|(x \otimes y.re) \otimes nrm|) \end{aligned}$$

We also get the analagous formula for the imaginary contribution for the error, so our total error is bounded by

$$\begin{aligned} &(2EPS)(1 + 3EPS/8 + (EPS/4)^2)(1 + EPS/2)((|(x \otimes y.re) \otimes nrm|) + (|(x \otimes y.im) \otimes nrm|)) \\ &\leq (2EPS)(1 + 3EPS/8 + (EPS/4)^2)(1 + EPS/2)^2((|(x \otimes y.re) \otimes nrm|) \oplus (|(x \otimes y.im) \otimes nrm|)) \\ &\leq (2EPS)(1 - EPS/2)(1 + 2EPS)((|(x \otimes y.re) \otimes nrm|) \oplus (|(x \otimes y.im) \otimes nrm|)) \end{aligned}$$

$$\leq (2EPS) \otimes ((1 + 2EPS) \otimes ((|(x \otimes y.re) \otimes nrm|) \oplus (|(x \otimes y.im) \otimes nrm|)))$$

Here we used the fact that

$$(1 + 3EPS/8 + (EPS/4)^2)(1 + EPS/2)^2 \leq (1 - EPS/2)(1 + 2EPS)$$

■

Proposition 7.12 (X / X):

$x/y = (re, im; e)$ where

$re = (x.re \otimes y.re \oplus x.im \otimes y.im) \otimes nrm$ where $nrm = y.re \otimes y.re \oplus y.im \otimes y.im$

$im = (x.im \otimes y.re \oplus x.re \otimes y.im) \otimes nrm$

$e = (5EPS/2) \otimes ((1 + 3EPS) \otimes A)$ where

$$A = ((|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \oplus (|x.im \otimes y.re| \oplus |x.re \otimes y.im|)) \otimes nrm$$

Proof:

It will be useful to begin by comparing $(a \times b + c \times d)/(e \times e + f \times f)$ with $(a \otimes b \oplus c \otimes d) \otimes nrm$.

Lemma 7.3:

$$|(a \otimes b \oplus c \otimes d) \otimes nrm - (a \times b + c \times d)/e \times e + f \times f|$$

$$\leq (EPS/2)(1 + EPS/2)(5 + 3EPS/2 + (EPS/2)^2)(|a \otimes b| \oplus |c \otimes d|)/nrm$$

Proof: At one point in the proof, we will use the fact that $|A \oplus B| \leq |A| \oplus |B|$. This fact is easily seen by considering the various possibilities for the sign of A versus the sign of B . At a different point in the proof, Lemma 7.2 with a, b replaced by e, f will be used.

$$|(a \otimes b \oplus c \otimes d) \otimes nrm - (a \times b + c \times d)/e \times e + f \times f|$$

$$\begin{aligned} &\leq |(a \otimes b \oplus c \otimes d) \otimes nrm - (a \otimes b \oplus c \otimes d)/nrm| \\ &\quad + |(a \otimes b \oplus c \otimes d)/nrm - (a \times b + c \times d)/(e \times e + f \times f)| \end{aligned}$$

$$\begin{aligned} &\leq (EPS/2)|a \otimes b \oplus c \otimes d|/nrm + |(a \otimes b \oplus c \otimes d)/nrm - (a \otimes b + c \otimes d)/nrm| \\ &\quad + |(a \otimes b + c \otimes d)/nrm - (a \times b + c \times d)/(e \times e + f \times f)| \end{aligned}$$

$$\begin{aligned} &\leq (EPS/2)|a \otimes b \oplus c \otimes d|/nrm + |(a \otimes b \oplus c \otimes d) - (a \otimes b + c \otimes d)|/nrm \\ &\quad + |(a \otimes b + c \otimes d)/nrm - (a \times b + c \times d)/nrm| \\ &\quad + |(a \times b + c \times d)/nrm - (a \times b + c \times d)/(e \times e + f \times f)| \end{aligned}$$

$$\begin{aligned}
 &\leq (EPS/2)|a \otimes b \oplus c \otimes d|/nrm + (EPS/2)|a \otimes b \oplus c \otimes d|/nrm \\
 &\quad + |(a \otimes b + c \otimes d)/nrm - (a \times b + c \times d)/nrm| \\
 &\quad + |(a \times b + c \times d)/nrm - (a \times b + c \times d)/(e \times e + f \times f)| \\
 &\leq (EPS/2)|a \otimes b \oplus c \otimes d|/nrm + (EPS/2)|a \otimes b \oplus c \otimes d|/nrm \\
 &\quad + |(a \otimes b - a \times b)/nrm - (c \otimes d - c \times d)/nrm| \\
 &\quad + (EPS + (EPS/2)^2)|(a \times b + c \times d)|/nrm \\
 &\leq (EPS)|a \otimes b \oplus c \otimes d|/nrm + (EPS/2)|a \otimes b|/nrm + (EPS/2)|c \otimes d|/nrm \\
 &\quad + (EPS + (EPS/2)^2)(1 + EPS/2)|(a \otimes b + c \otimes d)|/nrm \\
 &\leq (EPS)|a \otimes b \oplus c \otimes d|/nrm + (EPS/2)|a \otimes b|/nrm + (EPS/2)|c \otimes d|/nrm \\
 &\quad + (EPS + (EPS/2)^2)(1 + EPS/2)(|a \otimes b| + |c \otimes d|)/nrm \\
 &\leq (EPS)|a \otimes b \oplus c \otimes d|/nrm \\
 &\quad + (EPS/2 + (EPS + (EPS/2)^2)(1 + EPS/2))(|a \otimes b| + |c \otimes d|)/nrm \\
 &\leq (EPS)|a \otimes b \oplus c \otimes d|/nrm \\
 &\quad + (EPS/2)(1 + (2 + EPS/2)(1 + EPS/2))(|a \otimes b| + |c \otimes d|)/nrm \\
 &\leq (EPS)(|a \otimes b| \oplus |c \otimes d|)/nrm \\
 &\quad + (EPS/2)(3 + 3EPS/2 + (EPS/2)^2)(|a \otimes b| + |c \otimes d|)/nrm \\
 &\leq (EPS)(1 + EPS/2)(|a \otimes b| \oplus |c \otimes d|)/nrm \\
 &\quad + (EPS/2)(3 + 3EPS/2 + (EPS/2)^2)(1 + EPS/2)(|a \otimes b| \oplus |c \otimes d|)/nrm \\
 &\leq (EPS/2)(1 + EPS/2)(2 + (3 + 3EPS/2 + (EPS/2)^2))(|a \otimes b| \oplus |c \otimes d|)/nrm \\
 &\leq (EPS/2)(1 + EPS/2)(5 + 3EPS/2 + (EPS/2)^2)(|a \otimes b| \oplus |c \otimes d|)/nrm
 \end{aligned}$$

■

We now use this lemma to get the error term for X/X . Of course, this error is less than the sum of the real and imaginary errors. Also, we let

$$A = ((|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \oplus (|x.im \otimes y.re| \oplus |(-x.re) \otimes y.im|)) \odot nrm$$

$$\begin{aligned}
 & |(x.re \otimes y.re \oplus x.im \otimes y.im) \odot nrm - (x.re \times y.re + x.im \times y.im) / (y.re \times y.re + y.im \times y.im)| + \\
 & |(x.im \otimes y.re \oplus (-x.re) \otimes y.im) \odot nrm - (x.im \times y.re + (-x.re) \times y.im) / (y.re \times y.re + y.im \times y.im)| \\
 & \leq (EPS/2)(1 + EPS/2)(5 + 3EPS/2 + (EPS/2)^2)((|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \\
 & \quad + (|x.im \otimes y.re| \oplus |x.re \otimes y.im|)) / nrm \\
 & \leq (EPS/2)(1 + EPS/2)^3(5 + 3EPS/2 + (EPS/2)^2)((|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \\
 & \quad \oplus (|x.im \otimes y.re| \oplus |(-x.re) \otimes y.im|)) \odot nrm \\
 & = (EPS/2)(1 + EPS/2)^3(5 + 3EPS/2 + (EPS/2)^2)(A) \\
 & \leq (1 - (EPS/2))^2(5EPS/2)(1 + 3EPS)(A) \\
 & \leq (1 - (EPS/2))(5EPS/2)((1 + 3EPS) \otimes A) \\
 & \leq (5EPS/2) \otimes ((1 + 3EPS) \otimes A)
 \end{aligned}$$

Here we used the fact that

$$(1 + EPS/2)^3(5 + 3EPS/2 + (EPS/2)^2) \leq (1 - EPS/2)^2(5)(1 + 3EPS)$$

■

Proposition 7.13 (A / A):

$x/y = (re, im; e)$ where

$re = (x.re \otimes y.re \oplus x.im \otimes y.im) \odot nrm$ where $nrm = y.re \otimes y.re \oplus y.im \otimes y.im$

$im = (x.im \otimes y.re \oplus x.re \otimes y.im) \odot nrm$

$e = (1 + 4EPS) \otimes (((5EPS/2) \otimes A \oplus (1 + 103EPS) \otimes B) \odot nrm)$ where

$$A = (|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \oplus (|x.im \otimes y.re| \oplus |x.re \otimes y.im|)$$

$$B = x.e \otimes (|y.re| \oplus |y.im|) \oplus (|x.re| \oplus |x.im|) \otimes y.e$$

We are assuming (the computer will complain if this is not true) $y.e < 100EPS \otimes |y|$, or, more accurately,

$$y.e^2 < ((10000EPS) \otimes EPS) \otimes nrm.$$

Proof:

The error is bounded by $|x/y - x \odot y| + (\frac{x}{y}).e$ where

$$(\frac{x}{y}).e = \frac{|x| + x.e}{|y| - y.e} - \frac{|x|}{|y|}$$

$$\begin{aligned}
 &= \frac{|x||y| + |y|x.e - |x||y| + |x|y.e}{|y|(|y| - y.e)} \\
 &= \frac{|y|x.e + |x|y.e}{|y|(|y| - y.e)} \\
 &\leq (1 + 101EPS) \frac{|y|x.e + |x|y.e}{|y|^2}
 \end{aligned}$$

We have used the fact that our assertion $y.e^2 < (10000EPS \otimes EPS) \otimes nrm$ implies that

$$\frac{1}{|y|(|y| - y.e)} \leq (1 + 101EPS) \frac{1}{|y|^2},$$

which we derive in the next seven lines.

$$\begin{aligned}
 y.e^2 &< (10000EPS \otimes EPS) \otimes nrm \leq (1 + (EPS/2))(10000EPS \otimes EPS) \times nrm \\
 &\leq (1 + (EPS/2))^3 (10000EPS \otimes EPS) \times (y.re^2 + y.im^2) \\
 &\leq (1 + (EPS/2))^4 (10000EPS \times EPS) \times (y.re^2 + y.im^2) \\
 &= (1 + (EPS/2))^4 (100EPS)^2 \times |y|^2
 \end{aligned}$$

This implies that $y.e < A \times |y|$, where $A = (1 + (EPS/2))^2 (100EPS)$. Now, noting that $\frac{1}{1-A} \leq 1 + 101EPS$, we see that

$$\frac{1}{|y|(|y| - y.e)} \leq \frac{1}{|y|(|y| - A|y|)} = \frac{1}{|y|^2(1 - A)} \leq (1 + 101EPS) \frac{1}{|y|^2}$$

Resuming with our main proof, and setting

$$A = (|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \oplus (|x.im \otimes y.re| \oplus |x.re \otimes y.im|)$$

$$B = x.e \otimes (|y.re| \oplus |y.im|) \oplus (|x.re| \oplus |x.im|) \otimes y.e$$

we have that

$$\begin{aligned}
 &|x/y - x \odot y| + \left(\frac{x}{y}\right).e \\
 &\leq |x/y - x \odot y| + (1 + 101EPS) \frac{|y|x.e + |x|y.e}{|y|^2} \\
 &\leq (EPS/2)(1 + EPS/2)(5 + 3EPS/2 + (EPS/2)^2)((|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \\
 &\quad + (|x.im \otimes y.re| \oplus |x.re \otimes y.im|))/nrm \\
 &\quad + (1 + 101EPS)(x.e \times (|y.re| + |y.im|) + (|x.re| + |x.im|) \times y.e)/(|y|^2)
 \end{aligned}$$

$$\begin{aligned}
 &\leq (5EPS/2)(1 + EPS/2)^2(1 + (3EPS/10) + (EPS^2/20))(|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \\
 &\quad \oplus (|x.im \otimes y.re| \oplus |x.re \otimes y.im|)/nrm \\
 &\quad + (1 + 101EPS)(1 + EPS/2)(x.e \times (|y.re| \oplus |y.im|) \\
 &\quad \quad + (|x.re| \oplus |x.im|) \times y.e)/((\frac{1}{1 + EPS/2})^2 nrm) \\
 &\leq (5EPS/2)(1 + EPS/2)^3(|x.re \otimes y.re| \oplus |x.im \otimes y.im|) \\
 &\quad \oplus (|x.im \otimes y.re| \oplus |x.re \otimes y.im|)/nrm \\
 &\quad + (1 + 101EPS)(1 + EPS/2)^3(1 + EPS/2)^2(x.e \otimes (|y.re| \oplus |y.im|) \\
 &\quad \quad \oplus (|x.re| \oplus |x.im|) \otimes y.e)/nrm \\
 &= (1 + EPS/2)^3((5EPS/2)(A) + (1 + 101EPS)(1 + EPS/2)^2(B))/nrm \\
 &\quad (1 + EPS/2)^3((5EPS/2)A + (1 + 103EPS)B)/nrm \\
 &\quad (1 + EPS/2)^6(((5EPS/2) \otimes A \oplus (1 + 103EPS) \otimes B) \otimes nrm) \\
 &\quad (1 + 4EPS) \otimes (((5EPS/2) \otimes A \oplus (1 + 103EPS) \otimes B) \otimes nrm)
 \end{aligned}$$

Here we have used the fact that

$$(1 + EPS/2)^2(1 + (3EPS/10) + (EPS^2/20)) \leq (1 + (EPS/2)^3)$$

■

Proposition 7.14 ($\sqrt{X}$):

Let $s_o = \sqrt[3]{(|x.re| \oplus h_o(x.re, x.im)) \otimes 0.5}$ and $d_o = (x.im \otimes s) \otimes 0.5$, then $\sqrt{x} = (re, im; e)$ where

$$\begin{aligned}
 re &= s_o \text{ if } x.re > 0.0 \text{ and } re = d_o \text{ otherwise,} \\
 im &= d_o \text{ if } x.re > 0.0 \text{ and } im = s_o \text{ otherwise,} \\
 e &= EPS \otimes ((1 + 4EPS) \otimes (1.25 \otimes s_o \oplus 1.75 \otimes |d_o|))
 \end{aligned}$$

Proof:

This will be a little nasty. Let's begin by analyzing e_s , which is the difference between the true calculation of s and the machine calculation of s , that is $e_s = |s - s_o|$. First, we bound s .

$$\begin{aligned}
 s &= \sqrt{(|x.re| + h(x.re, x.im)) * 0.5} \\
 &\leq (1 + EPS)^{1/2} \sqrt{(|x.re| + h_o(x.re, x.im)) * 0.5} \\
 &\leq (1 + EPS)^{1/2} (1 + EPS/2)^{1/2} \sqrt{(|x.re| \oplus h_o(x.re, x.im)) * 0.5} \\
 &\leq (1 + EPS)^{1/2} (1 + EPS/2)^{1/2} (1 + EPS/2) \sqrt[3]{(|x.re| \oplus h_o(x.re, x.im)) * 0.5} \\
 &= (1 + EPS)^{1/2} (1 + EPS/2)^{3/2} s_o
 \end{aligned}$$

By a power series expansion, we see that

$$\begin{aligned}
 & (1 + EPS)^{1/2}(1 + EPS/2)^{3/2} \\
 &= (1 + \frac{1}{2}EPS - \frac{1}{8}EPS^2 + \dots) + (1 + \frac{3}{2}EPS/2 + \frac{3}{8}(EPS/2)^2 + \dots) \\
 &= (1 + \frac{1}{2}EPS - \frac{1}{8}EPS^2 + \dots) + (1 + \frac{3}{4}EPS + \frac{3}{32}(EPS)^2 + \dots) \\
 &= (1 + \frac{5}{4}EPS + \frac{11}{32}EPS^2 + \dots)
 \end{aligned}$$

So that,

$$s \leq (1 + \frac{5}{4}EPS + \frac{11}{32}EPS^2 + \dots)s_o$$

Similarly,

$$s \geq (1 - \frac{5}{4}EPS)s_o$$

Thus, we can bound the s error,

$$\begin{aligned}
 e_s &= |s - s_o| \\
 &\leq ((1 + \frac{5}{4}EPS + \frac{11}{32}EPS^2 + \dots) - 1)s_o \\
 &= (\frac{5}{4}EPS + \frac{11}{32}EPS^2 + \dots)s_o
 \end{aligned}$$

Next, we analyze e_d , which is the absolute value of the difference between the true calculation of d and the machine calculation of d . That is, $e_d = |d - d_o|$.

$$\begin{aligned}
 e_d &= |x.im/(2s) - x.im \odot (2s_o)| \\
 &\leq |x.im \odot (2s_o) - x.im/(2s_o)| + |x.im/(2s_o) - x.im/(2s)| \\
 &\leq (EPS/2)|x.im/(2s_o)| + |\frac{x.im}{2} \frac{s - s_o}{ss_o}| \\
 &\leq (EPS/2)|x.im/(2s_o)| + |\frac{x.im}{2} \frac{1}{ss_o}((5/4)EPS + (11/32)EPS^2 + \dots)s_o| \\
 &\leq (EPS/2)|x.im/(2s_o)| + |\frac{x.im}{2} \frac{1}{s}((5/4)EPS + (11/32)EPS^2 + \dots)| \\
 &\leq (EPS/2)|x.im/(2s_o)| + |\frac{x.im}{2} \frac{1}{s_o(1 - (5/4)EPS)}((5/4)EPS + (11/32)EPS^2 + \dots)| \\
 &= (EPS/2)|x.im/(2s_o)|(1 + \frac{(5/2) + (11/16)EPS + \dots}{(1 - (5/4)EPS)})
 \end{aligned}$$

$$\begin{aligned}
 &= (EPS/2) \frac{(7/2) + (-9/16)EPS + \dots}{(1 - (5/4)EPS)} |x.im/(2s_o)| \\
 &\leq (EPS/2)(1 + EPS/2) \frac{7/2}{(1 - (5/4)EPS)} |x.im \odot (2s_o)| \\
 &= (EPS/2)(1 + EPS/2) \frac{7/2}{(1 - (5/4)EPS)} |d_o|
 \end{aligned}$$

Finally, we can bound the overall error $e = e_s + e_d$.

$$\begin{aligned}
 &e_s + e_d \\
 &\leq \left(\frac{5}{4}EPS + \frac{11}{32}EPS^2 + \dots\right)s_o + (EPS/2)(1 + EPS/2) \frac{7/2}{(1 - (5/4)EPS)} |d_o| \\
 &\leq \left(EPS + \frac{11}{40}EPS^2 + \dots\right)\left(\frac{5}{4}s_o\right) + EPS(1 + EPS/2) \frac{1}{(1 - (5/4)EPS)} \left|\frac{7}{4}d_o\right| \\
 &\leq EPS(1 + EPS/2) \frac{1}{(1 - (5/4)EPS)} \left(\frac{5}{4}s_o\right) + EPS(1 + EPS/2) \frac{1}{(1 - (5/4)EPS)} \left|\frac{7}{4}d_o\right| \\
 &\leq EPS(1 + EPS/2) \frac{1}{(1 - (5/4)EPS)} \left(\frac{5}{4}s_o + \left|\frac{7}{4}d_o\right|\right) \\
 &\leq EPS(1 + EPS/2)^3 \frac{1}{(1 - (5/4)EPS)} \left(\frac{5}{4} \otimes s_o \oplus \left|\frac{7}{4} \otimes d_o\right|\right) \\
 &\leq EPS(1 - (EPS/2))(1 + 4EPS) \left(\frac{5}{4} \otimes s_o \oplus \left|\frac{7}{4} \otimes d_o\right|\right) \\
 &\leq EPS \otimes ((1 + 4EPS) \otimes \left(\frac{5}{4} \otimes s_o \oplus \left|\frac{7}{4} \otimes d_o\right|\right))
 \end{aligned}$$

■

Finally, we develop a couple of formulas for the absolute value of an XComplex.

Formula 7.0 (absUB(X)):

If x is an XComplex, then we get an upper bound on the absolute value of x as follows.

$$\begin{aligned}
 |x| &= h(x.re, x.im) \leq (1 + EPS)h_o(x.re, x.im) \\
 &\leq (1 - EPS/2)(1 + 2EPS)h_o(x.re, x.im) \\
 &\leq (1 + 2EPS) \otimes h_o(x.re, x.im)
 \end{aligned}$$

Thus, we define

$$absUB(x) = (1 + 2EPS) \otimes h_o(x.re, x.im)$$

■

Formula 7.1 (absLB(X)):

If x is an XComplex, then we get a lower bound on the absolute value of x as follows.

$$\begin{aligned} |x| &= h(x.re, x.im) \geq (1 - EPS)h_o(x.re, x.im) \\ &\geq (1 + EPS/2)(1 - 2EPS)h_o(x.re, x.im) \\ &\geq (1 - 2EPS) \otimes h_o(x.re, x.im) \end{aligned}$$

Thus, we define

$$absLB(x) = (1 - 2EPS) \otimes h_o(x.re, x.im)$$

■

Finally, in several places in the programs *verify* and *fudging* we perform a standard operation on a pair of doubles and must take into account round-off error. This is easy if we use Lemma 7.0.

For example, in *inequalityHolds* we want to show that $wh \times wh > absUB(along)$, where $wh = absLB(whirle)$. By Lemma 7.0, we know that $(1 - EPS) \otimes (wh \otimes wh) \leq wh \times wh$ and we simply test that $(1 - EPS) \otimes (wh \otimes wh) \geq absUB(along)$.

Similar situations occur in the functions *horizon* and *larger-angle* in *fudging*.

A slightly more complicated version of this occurs in the computer calculation of $pos[i]$ and $size[i]$, that is, the center and size of a sub-box. Prior to multiplication by $scale[i] = 2^{(5-i)/6}$, the calculations of pos and $size$ are exact. However, multiplication by $scale$ introduces round-off error. For the center of the box we will have the computer use $pos[i] \otimes scale[i]$ with the realization that this is not necessarily $pos[i] \times scale[i]$. Thus, we have to choose appropriate sizes to ensure that the machine sub-box contains the true sub-box.

Notationally, this is annoying, because we typically use a computer command like $pos[i] = pos[i] \otimes scale[i]$, while in an exposition, we need to avoid that. We will denote the true center of the box by $p[i]$ and the machine center of the box by $p_0[i]$, and the true and machine sizes will be denoted $s[i]$ and $s_0[i]$. We will let $pos[i]$ and $size[i]$ be the position and size (true and machine are the same) before multiplication by $scale[i]$.

Let $p[i] = pos[i] \times scale[i]$, $p_0[i] = pos[i] \otimes scale[i]$, and $s[i] = size[i] \times scale[i]$. We must select $s_0[i]$ so that $p_0[i] + s_0[i] \geq p[i] + s[i]$. (Here, taking $+$ on the left-hand side is correct, because the need for machine calculation there is incorporated at other points in the programs.) So, we must find $s_0[i]$ such that $s_0[i] \geq (p[i] - p_0[i]) + s[i]$.

$$\begin{aligned} (p[i] - p_0[i]) + s[i] &\leq (EPS/2)|p_0[i]| + size[i] \times scale[i] \\ &\leq (EPS/2)|p_0[i]| + (1 + EPS/2)(size[i] \otimes scale[i]) \\ &\leq (1 + EPS/2)((EPS/2)|p_0[i]| + (size[i] \otimes scale[i])) \\ &\leq (1 + EPS/2)^2((EPS/2)|p_0[i]| \oplus (size[i] \otimes scale[i])) \\ &\leq (1 + 2EPS) \otimes ((EPS/2)|p_0[i]| \oplus (size[i] \otimes scale[i])) \end{aligned}$$

Thus we take

$$s_0[i] = (1 + 2EPS) \otimes ((EPS/2)|p_0[i]| \oplus (size[i] \otimes scale[i]))$$

This also works to give $p_0[i] - s_0[i] \leq p[i] - s[i]$. ■

Chapter 8: AffApprox's with Round-Off Error

In Chapter 6, we saw how to do calculations with AffApprox's. In this chapter, we incorporate round-off error into these calculations.

Convention 8.1: Recall that an AffApprox x is a five-tuple $(x.f; x.f_0, x.f_1, x.f_2; x.err)$ consisting of four complex numbers $(x.f, x.f_0, x.f_1, x.f_2)$ and one real number $x.err$. In Chapter 6, the real number was denoted $x.e$, but it seems preferable to use $x.err$ in this Chapter. Also, we will suppress mention of the r functions used in Chapter 6 (see Definition 6.4). As such, statements in this section will have to be translated (implicitly) to account for this suppression.

Remark 8.2: One approach to round-off error for AffApprox's would be to replace the four complex numbers by four AComplex numbers complete with their round-off errors, and similarly for the one real number. We will not do this because it would necessitate keeping track of five separate round-off-error terms when we do AffApprox calculations.

Instead, we will replace the four complex numbers by four XComplex numbers ("exact" complex numbers) and push all the round-off error into the $.err$ term. In particular, in doing an AffApprox calculation, our subsidiary calculations will generally be on XComplex numbers and produce an AComplex number whose $.e$ term will be plucked off and forced into the $.err$ term of the final AffApprox.

Convention 8.3: In what follows, we will use Basic Properties 7.0 and Lemmas 7.0 and 7.1. Also, the Propositions in Chapter 6 will be utilized; as such, the numbering of the Propositions is the same in both Chapters (for example, Proposition 6.7 corresponds to Proposition 8.7).

-X:

Proposition 8.1: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$, then

$$-x = (-x.f; -x.f_0, -x.f_1, -x.f_2; x.err)$$

■

X + Y:

We analyze the addition of the AffApproxs $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ and $y = (y.f; y.f_0, y.f_1, y.f_2; y.err)$. To get the first term in $x + y$ we add the XComplex numbers $x.f$ and $y.f$; which produces the AComplex number $r_f = x.f + y.f$, and then we pluck off the XComplex part, $r_f.z$. The round-off error part $r_f.e$ will be foisted into the overall error term r_error for $x + y$. Similarly for the next three terms in $x + y$.

Abstractly, the overall error term r_error comes from adding the round-off error contributions $r_f.e$, $r_f_0.e$, $r_f_1.e$, $r_f_2.e$ and the AffApprox error contributions $x.err$, $y.err$. Of course, we have to produce a machine version.

Proposition 8.2: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ and $y = (y.f; y.f_0, y.f_1, y.f_2; y.err)$, then

$$x + y = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$$

where

$$r_error = (1 + 3EPS) \otimes ((x.e \oplus y.e) \oplus ((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)))$$

Proof: The error is given by

$$\begin{aligned} & (x.e + y.e) + ((r_f.e + r_f_0.e) + (r_f_1.e + r_f_2.e)) \\ & \leq (1 + EPS/2)(x.e \oplus y.e) + (1 + EPS/2)((r_f.e \oplus r_f_0.e) + (r_f_1.e \oplus r_f_2.e)) \\ & \leq (1 + EPS/2)^2(x.e \oplus y.e) + (1 + EPS/2)^2((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)) \\ & \leq (1 + EPS/2)^3((x.e \oplus y.e) \oplus ((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e))) \\ & \leq (1 + 3EPS) \otimes ((x.e \oplus y.e) \oplus ((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e))) \end{aligned}$$

To get the last line we used Lemma 1 in Section 5. $\blacksquare$

X - Y:

Proposition 8.3: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ and $y = (y.f; y.f_0, y.f_1, y.f_2; y.err)$, then

$$x - y = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$$

where

$$r_f = x.f - y.f$$

$$r_f_k = x.f_k - y.f_k$$

$$r_error = (1 + 3EPS) \otimes ((x.e \oplus y.e) \oplus ((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)))$$

$\blacksquare$

X + D

Here, we add the AffApprox $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ to the double y . The only terms that change are the first and the last.

Proposition 8.4: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ and y is a double, then

$$x + y = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$$

where

$$r_f = x.f + y$$

$$r_f_k = x.f_k$$

$$r_error = (1 + EPS) \otimes (x.err \oplus r_f.e)$$

Proof: The error is given by

$$x.err + r_f.e$$

$$\leq (1 + EPS) \otimes (x.err \oplus r_f.e)$$

by Lemma 0 in Section 5. $\blacksquare$

X - D

Proposition 8.5: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ and y is a double, then

$$x - y = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$$

where

$$r_f = x.f - y$$

$$r_f_k = x.f_k$$

$$r_f.z = x.f - y$$

$$r_error = (1 + EPS) \otimes (x.err \oplus r_f.e)$$

$\blacksquare$

X * Y

We multiply the AffApproxs x, y while pushing all error into the $.err$ term.

We will use the functions (see Formulas 7.0 and 7.1, at the end of Chapter 7) $absUB = (1 + 2EPS) \otimes hypot_o(x.re, x.im)$ and $absLB(x) = (1 - 2EPS) \otimes hypot_o(x.re, x.im)$.

When x is an AffApprox, we define $dist(x)$ to be

$$(1 + 2EPS) \otimes (absUB(x.f_0) \oplus (absUB(x.f_1) \oplus absUB(x.f_2))).$$

This is the machine representation of the sum of the absolute values of the linear terms in the AffApprox x (the proof is straightforward).

Proposition 8.6: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ and $y = (y.f; y.f_0, y.f_1, y.f_2; y.err)$, then

$$x * y = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$$

where

$$r_f = x.f \times y.f$$

$$r_f_k = x.f \times y.f_k + x.f_k \times y.f$$

Then, $x \times y = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$, where

$$r_error = (1 + 3EPS) \otimes (A \oplus (B \oplus C))$$

with

$$A = (dist(x) \oplus x.e) \otimes (dist(y) \oplus y.e)$$

$$B = absUB(x.f) \otimes y.e \oplus absUB(y.f) \otimes x.e$$

$$C = (r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)$$

Proof: We add the non-round-off error term for $x \times y$ to the various round-off error terms that accumulated.

$$\begin{aligned}
 & ((dist(x) + x.e) \times (dist(y) + y.e)) + ((absUB(x.f) \times y.e \\
 & \quad + absUB(y.f) \times x.e) + (r_f.e + r_f_0.e) + (r_f_1.e + r_f_2.e)) \\
 & \leq (1 + EPS/2)^2 [(dist(x) \oplus x.e) \times (dist(y) \oplus y.e)] + (1 + EPS/2)(absUB(x.f) \otimes y.e \\
 & \quad + absUB(y.f) \otimes x.e) + (1 + EPS/2)((r_f.e \oplus r_f_0.e) + (r_f_1.e \oplus r_f_2.e)) \\
 & \leq (1 + EPS/2)^3 [(dist(x) \oplus x.e) \otimes (dist(y) \oplus y.e)] + (1 + EPS/2)^2 \{ (absUB(x.f) \otimes y.e \\
 & \quad \oplus absUB(y.f) \otimes x.e) + ((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)) \} \\
 & \leq (1 + EPS/2)^3 A + (1 + EPS/2)^2 (B + C) \\
 & \leq (1 + EPS/2)^3 A + (1 + EPS/2)^3 (B + C) \\
 & \leq (1 + EPS/2)^4 (A \oplus (B + C)) \\
 & \leq (1 + 3EPS) \otimes (A \oplus (B + C))
 \end{aligned}$$

■

X * D:

Proposition 8.7: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ and y is a double, then

$$x \times y = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$$

where

$$r_f = x.f \times y$$

$$r_f_k = x.f_k \times y$$

$$r_error = (1 + 3EPS) \otimes ((x.e \otimes |y|) \oplus ((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)))$$

Proof:

$$\begin{aligned}
 & (x.e \times |y|) + ((r_f.e + r_f_0.e) + (r_f_1.e + r_f_2.e)) \\
 & \leq (1 + EPS/2)(x.e \otimes |y|) + (1 + EPS/2)((r_f.e \oplus r_f_0.e) + (r_f_1.e \oplus r_f_2.e)) \\
 & \leq (1 + EPS/2)^2 (x.e \otimes |y|) + (1 + EPS/2)^2 ((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)) \\
 & \leq (1 + EPS/2)^3 ((x.e \otimes |y|) \oplus ((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e))) \\
 & \leq (1 + 3EPS) \otimes ((x.e \otimes |y|) \oplus ((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)))
 \end{aligned}$$

■

X/Y:

For convenience, let $ax = \text{absUB}(x.f)$, $ay = \text{absLB}(y.f)$.

Proposition 8.8: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.\text{err})$ and $y = (y.f; y.f_0, y.f_1, y.f_2; y.\text{err})$, then

$$x/y = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$$

where

$$r_f = x.f/y.f$$

$$r_f_k = (x.f_k \times y.f - x.f \times y.f_k)/(y.f \times y.f)$$

$$r.\text{error} = (1 + 3EPS) \otimes (((1 + 3EPS) \otimes A \ominus (1 - 3EPS) \otimes B) \oplus C)$$

with

$$A = (ax \oplus (\text{dist}(x) \oplus x.e)) \otimes D$$

$$B = (ax \otimes ay \oplus \text{dist}(x) \otimes ay) \oplus ((\text{dist}(y) \otimes ax) \otimes (ay \otimes ay))$$

$$C = (r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)$$

$$D = ay \ominus (1 + EPS) \otimes (\text{dist}(y) \oplus y.e)$$

Of course, we do have to be concerned about division by zero, so the program will complain if ay is not greater than $(1 + EPS) \otimes (\text{dist}(y) \oplus y.e)$, that is, if D is not greater than zero.

Proof:

As usual, we add the round-off errors to the old AffApprox error, taking into account round-off error. Let's work on it bit by bit.

$$\begin{aligned} & (ax + \text{dist}(x) + x.e)/(ay - (\text{dist}(y) + y.e)) \\ & \leq (ax + (1 + EPS/2)(\text{dist}(x) \oplus x.e))/(ay - (1 + EPS) \otimes (\text{dist}(y) \oplus y.e)) \\ & \leq (1 + EPS/2)^2(ax \oplus (\text{dist}(x) \oplus x.e))/(ay - (1 + EPS) \otimes (\text{dist}(y) \oplus y.e)) \\ & \leq (1 + EPS/2)^2(ax \oplus (\text{dist}(x) \oplus x.e))/(\frac{1}{1 + EPS/2})(ay \ominus (1 + EPS) \otimes (\text{dist}(y) \oplus y.e)) \\ & \leq (1 + EPS/2)4(ax \oplus (\text{dist}(x) \oplus x.e)) \otimes (ay \ominus (1 + EPS) \otimes (\text{dist}(y) \oplus y.e)) \\ & = (1 + EPS/2)^4 A \\ & \leq (1 + 3EPS) \otimes A \end{aligned}$$

The next term, being subtracted, requires opposite inequalities.

$$\begin{aligned} & (ax/ay + \text{dist}(x)/ay) + \text{dist}(y) \times ax/(ay \times ay) \\ & \geq (1 - EPS/2)(ax \otimes ay + \text{dist}(x) \otimes ay) + (1 - EPS/2)(\text{dist}(y) \otimes ax)/(\frac{1}{1 - EPS/2})(ay \otimes ay) \end{aligned}$$

$$\begin{aligned}
 &\geq ((1 - EPS/2)^2(ax \otimes ay \oplus dist(x) \otimes ay) + (1 - EPS/2)^3(dist(y) \otimes ax) \otimes (ay \otimes ay)) \\
 &\quad \geq (1 - EPS/2)^3[(ax \otimes ay \oplus dist(x) \otimes ay) + (dist(y) \otimes ax) \otimes (ay \otimes ay)] \\
 &\geq ((1 - EPS/2)^4((ax \otimes ay \oplus dist(x) \otimes ay) \oplus ((dist(y) \otimes ax) \otimes (ay \otimes ay)))) \\
 &\quad \geq (1 + EPS/2)(1 + 3EPS)(B) \\
 &\quad \geq (1 - 3EPS) \otimes B
 \end{aligned}$$

Finally, we do the round-off terms.

$$\begin{aligned}
 &((r_f.e + r_f_0.e) + (r_f_1.e + r_f_2.e)) \\
 &\leq (1 + EPS/2)((r_f.e \oplus r_f_0.e) + (r_f_1.e \oplus r_f_2.e)) \\
 &\leq (1 + EPS/2)^2((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)) \\
 &\quad = (1 + EPS/2)^2 C
 \end{aligned}$$

Now, we put these three pieces together.

$$\begin{aligned}
 &(ax + dist(x) + x.e)/(ay - (dist(y) + y.e)) \\
 &- ((ax/ay + dist(x)/ay) + dist(y) \times ax/(ay \times ay)) + ((r_f.e + r_f_0.e) + (r_f_1.e + r_f_2.e)) \\
 &\leq (1 + 3EPS) \otimes A - (1 - 3EPS) \otimes B + (1 + EPS/2)^2 C \\
 &\leq (1 + EPS/2)((1 + 3EPS) \otimes A \ominus (1 - 3EPS) \otimes B) + (1 + EPS/2)^2 C \\
 &\leq (1 + EPS/2)^2(((1 + 3EPS) \otimes A \ominus (1 - 3EPS) \otimes B) + C) \\
 &\leq (1 + EPS/2)^3(((1 + 3EPS) \otimes A \ominus (1 - 3EPS) \otimes B) \oplus C) \\
 &\leq (1 + 3EPS) \otimes (((1 + 3EPS) \otimes A \ominus (1 - 3EPS) \otimes B) \oplus C)
 \end{aligned}$$

■

D/X:

We are dividing a double x by an AffApprox y . For convenience, let $ax = |x|$, $ay = absLB(y.f)$.

Proposition 8.9: If x is a double, and $y = (y.f; y.f_0, y.f_1, y.f_2; y.err)$, then

$$x/y = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$$

where

$$\begin{aligned}
 r_f &= x/y.f \\
 r_f_k &= -(x \times y.f_k)/(y.f \times y.f) \\
 r_error &= (1 + 3EPS) \otimes (((1 + 2EPS) \otimes (ax \otimes D) \ominus (1 - 3EPS) \otimes B) \oplus C)
 \end{aligned}$$

$$B = ax \oslash ay \oplus (dist(y) \otimes ax \oslash (ay \otimes ay))$$

$$C = (r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)$$

$$D = ay \ominus (1 + EPS) \otimes (dist(y) \oplus y.e)$$

Again, we have to be concerned about division by zero, so the program will complain if ay is not greater than $(1 + EPS) \otimes (dist(y) \oplus y.e)$, that is if D is not greater than zero.

Proof:

Let's start with the pieces.

$$\begin{aligned} & ax / (ay - (dist(y) + y.e)) \\ & \leq ax / (ay - (1 + EPS) \otimes (dist(y) \oplus y.e)) \\ & \leq ax / (\frac{1}{1 + EPS/2})(ay \ominus (1 + EPS) \otimes (dist(y) \oplus y.e)) \\ & \leq (1 + EPS/2)^2 ax \oslash D \\ & \leq (1 + 2EPS) \otimes (ax \oslash D) \end{aligned}$$

The next term, being subtracted, requires opposite inequalities.

$$\begin{aligned} & ax / ay + dist(y) \times ax / (ay \times ay) \\ & \geq (1 - EPS/2) ax \oslash ay + (1 - EPS/2) dist(y) \otimes ax / (\frac{1}{1 - EPS/2})(ay \otimes ay) \\ & \geq (1 - EPS/2) ax \oslash ay + (1 - EPS/2)^3 dist(y) \otimes ax \oslash (ay \otimes ay) \\ & \geq (1 - EPS/2)^3 (ax \oslash ay + dist(y) \otimes ax \oslash (ay \otimes ay)) \\ & \geq (1 - EPS/2)^4 [ax \oslash ay \oplus (dist(y) \otimes ax \oslash (ay \otimes ay))] \\ & \geq (1 + EPS/2)(1 - 3EPS) B \\ & \geq (1 - 3EPS) \otimes B \end{aligned}$$

Finally, we do the round-off terms as before.

$$\begin{aligned} & ((r_f.e + r_f_0.e) + (r_f_1.e + r_f_2.e)) \\ & \leq (1 + EPS/2)^2 C \end{aligned}$$

Putting the pieces together, we have:

$$\begin{aligned} & \leq ax / (ay - (dist(y) + y.e)) \\ & \quad - (ax / ay + dist(y) \times ax / (ay \times ay)) + ((r_f.e + r_f_0.e) + (r_f_1.e + r_f_2.e)) \\ & \leq (1 + 2EPS) \otimes (ax \oslash D) - (1 - 3EPS) \otimes B + (1 + EPS/2)^2 C \end{aligned}$$

$$\begin{aligned}
 &\leq (1 + EPS/2)((1 + 2EPS) \otimes (ax \otimes D) \ominus (1 - 3EPS) \otimes B) + (1 + EPS/2)^2 C \\
 &\leq (1 + EPS/2)^2(((1 + 2EPS) \otimes (ax \otimes D) \ominus (1 - 3EPS) \otimes B) + C) \\
 &\leq (1 + EPS/2)^3(((1 + 2EPS) \otimes (ax \otimes D) \ominus (1 - 3EPS) \otimes B) \oplus C) \\
 &\leq (1 + 3EPS) \otimes (((1 + 2EPS) \otimes (ax \otimes D) \ominus (1 - 3EPS) \otimes B) \oplus C)
 \end{aligned}$$

■

X/D:

We are dividing an AffApprox x by a double y and the computer will object if $y = 0$.

Proposition 8.10: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ and y is a double, then

$$x/y = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$$

where

$$\begin{aligned}
 r_f &= x.f/y \\
 r_f_k &= x.f_k/y \\
 r_error &= (1 + 3EPS) \otimes ((x.e \otimes |y|) \oplus [(r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)])
 \end{aligned}$$

Proof:

This is easy.

$$\begin{aligned}
 &x.e/|y| + ((r_f.e + r_f_0.e) + (r_f_1.e + r_f_2.e)) \\
 &\leq (1 + EPS/2)x.e \otimes |y| + (1 + EPS/2)^2[(r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)] \\
 &\leq (1 + EPS/2)^2(x.e \otimes |y| + [(r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)]) \\
 &\leq (1 + EPS/2)^3(x.e \otimes |y| \oplus [(r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)]) \\
 &\leq (1 + 3EPS) \otimes (x.e \otimes |y| \oplus [(r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)])
 \end{aligned}$$

■

$\sqrt{X}$:

Here, x is an AffApprox and we let $ax = absUB(x.f)$. There are two cases to consider depending on whether or not $D = ax \ominus (1 + EPS) \otimes (dist(x) \oplus x.e)$ is or is not greater than zero.

Proposition 8.11a: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ and D is not greater than zero, then we use the crude over-estimate $\sqrt{x} = (0; 0, 0, 0; (1 + 2EPS) \otimes \sqrt[3]{(ax \oplus (x.dist \oplus x.e))})$

Proof:

$$\begin{aligned}
 &\sqrt{ax + x.dist + x.e} \\
 &\leq \sqrt{ax + (1 + EPS/2)(x.dist \oplus x.e)}
 \end{aligned}$$

$$\begin{aligned}
 &\leq \sqrt{(1 + EPS/2)^2(ax \oplus (x\text{dist} \oplus x.e))} \\
 &= (1 + EPS/2)\sqrt{(ax \oplus (x\text{dist} \oplus x.e))} \\
 &\leq (1 + EPS/2)^2 \sqrt[3]{(ax \oplus (x\text{dist} \oplus x.e))} \\
 &\leq (1 + 2EPS) \otimes \sqrt[3]{(ax \oplus (x\text{dist} \oplus x.e))}
 \end{aligned}$$

■

Proposition 8.11b: If $x = (x.f; x.f_0, x.f_1, x.f_2; x.err)$ and D is greater than zero, then,

$$\sqrt{x} = (r_f.z; r_f_0.z, r_f_1.z, r_f_2.z; r_error)$$

where

$$r_f = \sqrt{x.f}$$

$$t = r_f + r_f$$

$$r_f_k = \text{AComplex}(x.f_k.re, x.f_k.im, 0)/t$$

(Simply put, $r_f_k = x.f_k/(2\sqrt{x.f})$. The reason we have to fuss to define r_f_k is because $\sqrt{x.f}$ is an AComplex.)

$$\begin{aligned}
 r_error = (1 + 3EPS) \otimes (& \\
 & \{(1 + EPS) \otimes \sqrt[3]{ax} \\
 \ominus (1 - 3EPS) \otimes [dist(x) \otimes (2 \times \sqrt[3]{ax}) \oplus \sqrt[3]{D}]\} & \\
 \oplus ((r_f.e \oplus r_f_0.e) \oplus (r_f_1.e \oplus r_f_2.e)) & \\
) &
 \end{aligned}$$

Proof:

Let's work on the pieces.

$$\sqrt{ax} \leq (1 + EPS) \otimes \sqrt[3]{ax}$$

Next,

$$\begin{aligned}
 &dist(x)/(2\sqrt{ax}) + \sqrt{ax - (dist(x) + x.e)} \\
 &\geq (1 - EPS/2)^2 dist(x) \otimes (2\sqrt[3]{ax}) + \sqrt{ax - (1 + EPS) \otimes (dist(x) \oplus x.e)} \\
 &\geq (1 - EPS/2)^2 dist(x) \otimes (2\sqrt[3]{ax}) \\
 &\quad + (1 - EPS/2)^{1/2} \sqrt{ax \ominus (1 + EPS) \otimes (dist(x) \oplus x.e)} \\
 &\geq (1 - EPS/2)^2 dist(x) \otimes (2\sqrt[3]{ax}) + (1 - EPS/2)^{3/2} \sqrt[3]{D} \\
 &\geq (1 - EPS/2)^2 [dist(x) \otimes (2\sqrt[3]{ax}) + \sqrt[3]{D}] \\
 &\geq (1 - EPS/2)^3 [dist(x) \otimes (2\sqrt[3]{ax}) \oplus \sqrt[3]{D}]
 \end{aligned}$$

$$\begin{aligned} &\geq (1 + EPS/2)(1 - 3EPS)[dist(x) \oslash (2\sqrt[3]{ax}) \oplus \sqrt[3]{D}] \\ &\geq (1 - 3EPS) \otimes [dist(x) \oslash (2\sqrt[3]{ax}) \oplus \sqrt[3]{D}] \end{aligned}$$

Adding in the usual term, we get as our error bound

$$\begin{aligned} &\sqrt{ax} - (dist(x)/(2\sqrt{ax}) + \sqrt{ax - (dist(x) + x.e)}) + ((r_{-f}.e + r_{-f_0}.e) + (r_{-f_1}.e + r_{-f_2}.e)) \\ &\leq (1 + EPS) \otimes \sqrt[3]{ax} \\ &\quad - (1 - 3EPS) \otimes [dist(x) \oslash (2\sqrt[3]{ax}) \oplus \sqrt[3]{D}] \\ &\quad + (1 + EPS/2)^2((r_{-f}.e \oplus r_{-f_0}.e) \oplus (r_{-f_1}.e \oplus r_{-f_2}.e)) \\ &\leq (1 + EPS/2)\{(1 + EPS) \otimes \sqrt[3]{ax} \\ &\quad \ominus (1 - 3EPS) \otimes [dist(x) \oslash (2\sqrt[3]{ax}) \oplus \sqrt[3]{D}]\} \\ &\quad + (1 + EPS/2)^2((r_{-f}.e \oplus r_{-f_0}.e) \oplus (r_{-f_1}.e \oplus r_{-f_2}.e)) \\ &\leq (1 + EPS/2)^3\{(1 + EPS) \otimes \sqrt[3]{ax} \\ &\quad \ominus (1 - 3EPS) \otimes [dist(x) \oslash (2\sqrt[3]{ax}) \oplus \sqrt[3]{D}]\} \\ &\quad \oplus ((r_{-f}.e \oplus r_{-f_0}.e) \oplus (r_{-f_1}.e \oplus r_{-f_2}.e)) \\ &\leq (1 + 3EPS) \otimes (\{(1 + EPS) \otimes \sqrt[3]{ax} \\ &\quad \ominus (1 - 3EPS) \otimes [dist(x) \oslash (2\sqrt[3]{ax}) \\ &\quad \oplus \sqrt[3]{D}]\} \oplus ((r_{-f}.e \oplus r_{-f_0}.e) \oplus (r_{-f_1}.e \oplus r_{-f_2}.e))) \end{aligned}$$
